#### Abstract

In this paper we are concerned with the issue of the existence of locally uniform Edgeworth expansions for the distributions of parameterized random vectors. Our motivation resides on the fact that this could enable subsequent polynomial asymptotic expansions of moments. These could be useful for the establishment of asymptotic properties for estimators based on these moments. We derive sufficient conditions either in the case of stochastic processes exhibiting weak dependence, or in the case of smooth transformations of such expansions.

KEYWORDS: Locally uniform Edgeworth expansion, formal Edgeworth distribution, weak dependence, smooth transformations, moment approximations, GMM estimators, Indirect estimators, GARCH model.

JEL: C10, C13

## 1 Introduction

In this paper we are concerned with the issue of the approximation of the distributions of a sequence of random vectors by sequences of Edgeworth distributions uniformly with respect to a compact valued Euclidean parameter. Our motivation resides on the fact that the uniformity could enable subsequent polynomial asymptotic expansions of analogous moments with respect to appropriate sequences of the aforementioned parameter (see for example lemma 2.3 of Arvanitis and Demos [1]). This in turn can facilitate
the extraction of higher order asymptotic properties of estimators that are defined by the use of such moments. A prominent example is the indirect estimator defined by Gourieroux et al. 10 (abbreviated as GMR2 estimator in Arvanitis and Demos [1], definition D.3.) as a minimizer of a criterion involving the expectation of an auxiliary estimator (see in particular the last part of the proof of lemma 4.2).

We will hereafter refer to the aforementioned approximation as a locally uniform Edgeworth expansion of the involved random vectors. We notice that analogous expansions have been studied by Bhattacharya and Ghosh [3] (see Theorem 3) in the iid case and Durbin [7] for the case where the random vectors are of the form of $\sqrt{n}$ times an arithmetic mean.

In what follows we will provide sufficient conditions for the existence of such an approximation in two cases. The first concerns the one where the random vectors are of the form of $\sqrt{n}$ times an arithmetic mean, the elements of which are members of a stochastic process exhibiting weak dependence, in the spirit of Gotze and Hipp [9. There, the authors validate the pointwise (w.r.t. the parameter) formal Edgeworth expansions. We essentially follow their line of reasoning, whereby by strengthening their conditions we establish the result ensuring that the relevant remainders are independent of the parameter. In the second case we assume that a locally uniform Edgeworth expansion is valid, and given a sequence of smooth transformations for the random vector at hand, we provide sufficient conditions for an analogous expansion to exist for the transformed random vector. In this case our line of reasoning is close to the one in Skovgaard [14], but compared to this paper we utilize additional conditions concerning the dependence of the transformations on the parameter. Obviously these can be recursively used for the establishment of valid locally uniform Edgeworth expansions in composite cases.

The structure of the paper is as follows. In the next two sections we are concerned with the aforementioned cases respectively. In the fourth section we provide a simple example concerning a GARCH model involving estimators for the asymptotic analysis of which we utilize all the previous results. In the final section we conclude.

## 2 Valid Locally Uniform Formal Edgeworth Expansions Under Weak Dependence

In the following we denote with $\Theta$ a compact subset of $\mathbb{R}^{p}$ (w.r.t. the usual topology). The following assumption defines the form of the eligible stochas-
tic processes for the results that follow.
Assumption A. 1 Let $\left(\varepsilon_{j}\right)$ be a sequence of iid random variables, $g: \mathbb{R}^{\mathbb{N}} \times$ $\Theta \rightarrow \mathbb{R}$ and $h: \mathbb{R}^{p} \times \Theta \rightarrow \mathbb{R}^{k}$ be Borel (jointly) measurable functions and suppose that $h$ has uniformly equicontinuous (w.r.t. $\Theta$ ) first order derivative w.r.t. $\left(Z_{j}, \ldots, Z_{j+p-1}\right)$. Define for $j \in \mathbb{Z}, \theta \in \Theta$

$$
\begin{align*}
& Z_{j}:=g\left(\varepsilon_{j-i}: i \geq 0, \theta\right)  \tag{1}\\
& X_{j}:=h\left(Z_{j}, \ldots, Z_{j+p-1}, \theta\right)
\end{align*}
$$

where $\sup _{\theta \in \Theta} E\left\|D_{Z} h\left(Z_{i}, \ldots, Z_{i+p-1}, \theta\right)\right\| \leq K$ for some constant $K>0$.
During this section, we occasionally suppress the dependence of $Z_{j}$ and $X_{j}$ on $\theta$ for notational simplicity. Now, let $S_{n}(\theta)=\frac{1}{\sqrt{n}} \sum_{i=1}^{n}\left(X_{i}(\theta)-E X_{0}(\theta)\right)$, for $r=0, \ldots, s$ let $\chi_{r, n}(t)$ be the cumulants of $t^{T} S_{n}$ of order $r$, i.e.

$$
\chi_{r, n}(t)=\left.\frac{d^{r}}{d x^{r}} \log E \exp \left(i x t^{T} S_{n}\right)\right|_{x=0}
$$

Obviously $\chi_{r, n}$ depend on $\theta$. Let $\Psi_{n, s}(t)$ be the formal Edgeworth measure of $S_{n}$ of order $s-2, s \geq 3$, defined by its characteristic function $\widehat{\Psi}_{n, s}(t)=$ $\exp \left(\chi_{2, s}\right)+\sum_{r=1}^{s-2} n^{-r / 2} \widetilde{P}_{r, n}(t)$, where the functions $\widetilde{P}_{r, n}(t), r=1,2, \ldots$ satisfy the formal identity

$$
\exp \left(\chi_{2, n}+\sum_{r=3}^{\infty} \frac{1}{r!} \tau^{r-2} n^{(r-2) / 2} \chi_{r, n}(t)\right)=\exp \left(\chi_{2, s}\right)+\sum_{r=1}^{\infty} \tau^{r} \widetilde{P}_{r, n}(t)
$$

and $\mathcal{B}_{c}$ the collection of convex Borel set of $\mathbb{R}^{k}$.
Question Given A.1, under what conditions

$$
\begin{equation*}
\sup _{\theta \in \Theta} \sup _{A \in \mathcal{B}_{c}}\left|P\left(S_{n}(\theta) \in A\right)-\Psi_{n, s}(\theta)(A)\right|=o\left(n^{\frac{s-2}{2}}\right) \tag{2}
\end{equation*}
$$

The next assumption provides sufficient conditions so that the previous question is well-posed and has an affirmative answer. It essentially corresponds to a uniform extension of the analogous conditions (2)-(4) in Gotze and Hipp [9]. The proof of sufficiency follows naturally the line of proof of Theorem 1.1 of Gotze and Hipp [9, by establishing that due to assumption A. 2 the terms appearing in the relevant bounds are independent of $\theta$.

Assumption A. 2 Let the following conditions hold:
-M (Existence of Moments)

$$
\sup _{\theta \in \Theta} E\left\|X_{1}\right\|^{s+1} \leq \beta_{s+1}
$$

-WD (Weak Dependence) There exist constants $K<\infty$ and $\alpha>0$ independent of $\theta$ such that for $m \geq 1$,

$$
E\left\|g\left(\varepsilon_{j}: j \geq 0, \theta\right)-g\left(\varepsilon_{0}, \ldots, \varepsilon_{m}, 0, \ldots, \theta\right)\right\| \leq K \exp (-\alpha m)
$$

-SM (Smoothness) There exist $\alpha>0$ independent of $\theta$ and $r>0$ such that for arbitrary large fixed $\kappa>1$ and all $n>m>\alpha^{-1}$ and $t \in \mathbb{R}^{k}$ with $n^{\kappa}>\|t\|>\alpha$,

$$
E\left|E \left(\exp \left(\sqrt{-1} t^{\prime}\left(X_{0}+\ldots+X_{2 m}\right)\right)\left|\varepsilon_{j}:|j-m| \geq r\right) \mid \leq \exp (-\alpha)\right.\right.
$$

The next theorem provides the required result.
Theorem 2.1 If assumptions A.1 and A. 2 are valid then equation 2 holds.

Auxiliary Lemmas For the proof of the previous theorem we will need the following auxiliary results. First, we denote with $\mathcal{D}_{j+p-1-m, j+p+1}$ the $\sigma$-algebra generated by $\left(\varepsilon_{j+p-1-m}, \ldots, \varepsilon_{j+p+1}\right)$ which is obviously independent of $\theta$ and satisfies conditions (2.4) and (2.6) of Gotze and Hipp [8] for any $m, n, p$ due to the definition of $\left(\varepsilon_{j}\right)$ in assumption A.1. The first auxiliary result is the uniform extension of Lemma 2.1 of Gotze and Hipp 9 .

Lemma 2.2 Under assumptions A.1, A.2-M and A.2-WD there exist a constant $K_{1}$ independent of $\theta$ and $a$ (for any $\theta \in \Theta$ ) $\mathcal{D}_{j+p-1-m, j+p+1}-m e a s u r a b l e$ random element $X_{j}^{*}$ such that

$$
\begin{equation*}
\sup _{\theta \in \Theta} E\left\|X_{j}-X_{j}^{*}\right\| \leq K_{1} \exp \left[-\alpha \frac{s}{3(s+1)} m\right] \tag{3}
\end{equation*}
$$

Furthermore under assumptions A. 1 and A. 2 we have that

$$
\begin{equation*}
\inf _{\theta \in \Theta} \lim \inf _{n} \inf _{\|t\|=\alpha} \operatorname{var}\left(t^{\prime} S_{n}(\theta)\right)>0 \tag{4}
\end{equation*}
$$

Remark R. 1 It is easy to see that equation 4 implies that $\inf _{\theta \in \Theta} \liminf _{n} \lambda_{n}^{\min }(\theta)>$ 0 where $\lambda_{n}^{\min }(\theta)$ denotes the minimum eigenvalue of $\operatorname{var}\left(S_{n}(\theta)\right)$ implying that they are uniformly positive definite. Suppose the contrary, i.e. there exists $x \neq 0_{k}$ for which $\inf _{\theta \in \Theta} \liminf _{n} x^{\prime} \operatorname{var}\left(S_{n}(\theta)\right) x=0$. Then let $z=\frac{a}{\|x\|} x$ and $0=\frac{\|x\|^{2}}{a^{2}} \inf _{\theta \in \Theta} \lim _{\inf }^{n} \operatorname{var}\left(z^{\prime} S_{n}(\theta)\right)$ which is impossible due to equation 4.

Proof of Lemma 2.2. (For analytic proof see Arvanitis and Demos [2]) Let $g_{0}$ be the composition of $h(\cdot, \theta)$ and $g(\cdot, \theta)$ such that $X_{j}=g_{0}\left(\varepsilon_{j+p-l}: l \geq 0, \theta\right)$. For $m>p-1$ let

$$
X_{j}^{\prime}(\theta):=g_{0}\left(\varepsilon_{j+p-1}, \ldots, \varepsilon_{j-m+p-1}, 0, \ldots, \theta\right) .
$$

Define the obviously $\mathcal{D}_{j+p-1-m, j+p+1}$-measurable random element $X_{j}^{*}(\theta)$

$$
X_{j}^{*}(\theta)=X_{j}^{\prime}(\theta) I\left(\left\|X_{j}^{\prime}(\theta)\right\| \leq a_{m}^{\frac{1}{s+1}}\right)
$$

where $a_{m}=\exp \left(\frac{\alpha m}{3}\right)$. Further, let $B_{m}$ be the set of sequences of $\varepsilon_{j}$ such that

$$
\sup _{\theta \in \Theta}\left\|D_{Z} h\left(Z_{j}, \ldots, Z_{j+p-1}, \theta\right)\right\| \leq K a_{m}
$$

and

$$
\sup _{\theta \in \Theta}\left\|Z_{j+v}-g\left(\varepsilon_{j+v}, \ldots, \varepsilon_{j+v-m}, 0, \ldots, \theta\right)\right\| \leq K \exp \left[\frac{\alpha m}{3}-\alpha(m-v)\right]
$$

Due to the uniform equicontinuity, assumption A.1, there exist $m_{0}$ such that for $m \geq m_{0}$ and $\varepsilon_{j}, j \in \mathbb{Z}$, in $B_{m}, \sup _{\theta \in \Theta}\left\|D_{Z} h\right\| \leq K \exp \left(\frac{\alpha m}{3}\right)$ on the segment connecting the $Z$ vectors of the infinite and truncated (at $m$ ) sequence of $\varepsilon_{j}$ for any $\theta \in \Theta$. Now,

$$
E\left\|X_{j}-X_{j}^{*}\right\| \leq 2 E\left\|X_{j}\right\|^{s+1} a_{m}^{-s /(s+1)}+E\left\|X_{j}-X_{j}^{*}\right\| 1_{\left\|X_{j}\right\| \leq a_{m}^{1 /(s+1)}}
$$

since $\left\|X_{j}\right\|>a_{m}^{1 /(s+1)} \Leftrightarrow\left\|X_{j}\right\|<\left\|X_{j}\right\|^{s+1} a_{m}^{-s /(s+1)}$ and $P\left(\left\|X_{j}\right\|>a_{m}^{1 /(s+1)}\right) \leq$ $E\left\|X_{j}\right\|^{s+1} a_{m}^{-(s+1) /(s+1)}$ due to Markov's inequality. Also

$$
E\left\|X_{j}-X_{j}^{*}\right\| 1_{\left\|X_{j}\right\| \leq a_{m}^{1 /(s+1)}}=E\left\|X_{j}-X_{j}^{*}\right\| 1_{\left\|X_{j}\right\| \leq a_{m}^{1 /(s+1)}} 1_{B_{m}}+E\left\|X_{j}-X_{j}^{*}\right\| 1_{\left\|X_{j}\right\| \leq a_{m}^{1 /(s+1)}} 1_{B_{m}^{c}}
$$

and

$$
\begin{aligned}
B_{m}^{c} \subseteq & \left\{(\varepsilon): \sup _{\theta \in \Theta}\left\|D h\left(Z_{j}, \ldots, Z_{j+p-1}, \theta\right)\right\|>K a_{m}\right\} \\
& \cup\left\{(\varepsilon):\left\|Z_{t+p}-g\left(\varepsilon_{j+p}, \ldots, \varepsilon_{j+p-m}, 0, \ldots, \theta\right)\right\|>K a_{m} \exp (-a(m-p))\right\} .
\end{aligned}
$$

Due to equation (1) and the fact that $\alpha>0$ we have that for any $m$

$$
P\left(\left\{(\varepsilon): \sup _{\theta \in \Theta}\left\|D h\left(X_{j}, \ldots, X_{j+p}\right)\right\|>K a_{m}\right\}\right)=0
$$

and that due to assumption A.2.WD and the inequality of Markov $P\left(\left\|Z_{t+p}-g\left(\varepsilon_{j+p}, \ldots, \varepsilon_{j+p-m}, 0, \ldots, \theta\right)\right\|>K a_{m} \exp (-\alpha(m-p))\right) \leq \exp (-\alpha p) a_{m}^{-\frac{s+1}{s+1}}$.

Hence

$$
P\left(B_{m}^{c}\right) \leq \exp (-\alpha p) a_{m}^{-\frac{s+1}{s+1}}
$$

and therefore

$$
E\left\|X_{j}-X_{j}^{*}\right\| 1_{\left\|X_{j}\right\| \leq a_{m}^{1 /(s+1)}} 1_{B_{m}^{c}} \leq 2 \exp (-\alpha p) a_{m}^{-\frac{s}{s+1}} .
$$

Finally due to the Mean Value Theorem and the fact that $1_{\left\|X_{j}\right\| \leq a_{m}^{1 /(s+1)}} 1_{B_{m}}=$ 1 means that $1_{\left\|X_{j}^{\prime}\right\| \leq a_{m}^{1 /(s+1)}}=1$

$$
E\left\|X_{j}-X_{j}^{*}\right\| 1_{\left\|X_{j}\right\| \leq a_{m}^{1 /(s+1)}} 1_{B_{m}} \leq C^{*} a_{m}^{-1}
$$

for $C^{*}=p C K^{2} \frac{\exp (p \alpha)-\exp (\alpha)}{\exp (\alpha)-1} P\left(B_{m}\right)>0$ and independent of $\theta$. Hence

$$
E\left\|X_{j}-X_{j}^{*}\right\| \leq K_{1} a_{m}^{-\frac{s}{s+1}}
$$

where $K_{1}=2 E\left\|X_{j}\right\|^{s+1}+2 \exp (-\alpha p)+C^{*} a_{m}^{-\frac{1}{s+1}}$ independent of $\theta$.
Now let $\gamma=\frac{s-1}{2 s}$ and $C_{s, \alpha}=\frac{1}{1-\exp (-2 \gamma)} \sqrt{\frac{1-\exp (-2 \alpha)}{2}}$ and $q=r+1+\left\lfloor\frac{1}{\gamma \alpha} \log \left(K_{1} \alpha^{s+3} C_{s, \alpha} E^{\frac{1}{s}}\left\|X_{1}\right\|^{s+1}\right)\right\rfloor$, where $\lfloor x\rfloor$ denotes the integral part of $x$. Notice that all constants, $\gamma, C_{s, \alpha}$ and $q$, are independent of $\theta$. For $n \geq 2 q$ let $\mathcal{D}_{j}$ denote the $\sigma$-algebra generated by $\varepsilon_{l}, l \leq j q+p-1$, and define

$$
\Delta_{j}=n^{1 / 2} t^{\prime}\left[E\left(S_{n} \mid \mathcal{D}_{j}\right)-E\left(S_{n} \mid \mathcal{D}_{j-1}\right)\right]
$$

Writing $n=L q+N$ with $N<q$, the following variance decomposition holds:

$$
\operatorname{var}\left(t^{\prime} S_{n}\right)=n^{-1} \sum_{j=1}^{L} E \Delta_{j}^{2}+E\left[t^{\prime}\left(S_{n}-E\left(S_{n} \mid \varepsilon_{l}, l \leq n+p-1-N\right)\right)\right]^{2}
$$

Since $X_{v}, v \leq j q$, are $\mathcal{D}_{j}$-measurable for any $\theta \in \Theta$, we obtain

$$
\begin{aligned}
\Delta_{j} & =t^{\prime}\left[\sum_{v=j q-q+1}^{j q-1}\left(X_{v}-E\left(X_{v} \mid \mathcal{F}_{j-1}\right)\right)+\sum_{v=j q}^{n}\left(E\left(X_{v} \mid \mathcal{F}_{j}\right)-E\left(X_{v} \mid \mathcal{F}_{j-1}\right)\right)\right] \\
& \doteqdot V_{j}+R_{j} .
\end{aligned}
$$

Define $\varepsilon_{v, M}=\left(\varepsilon_{v+p-1}, \varepsilon_{v+p-2}, \ldots, \varepsilon_{M q+p-1}, 0, \ldots\right)$ for $v \geq M q$ and $\varepsilon_{v}=$ $\left(\varepsilon_{v+p-l}: l \geq 1\right)$. We have that

$$
E^{1 / 2} \Delta_{j}^{2} \geq E^{1 / 2} V_{j}^{2}-E^{1 / 2} R_{j}^{2}
$$

and employing Holder's inequality and the definition of $q$ we get

$$
E R_{j}^{2} \leq \frac{1}{2}(1-\exp (-2 \alpha \gamma))
$$

independent of $\theta$. On the other hand the inequality $x^{2} / 2 \geq 2 \sin ^{2}(x / 2)=$ $1-\cos (x)$ together with

$$
\operatorname{var}(Z)=\frac{1}{2} E\left(Z-Z^{*}\right)^{2} \geq 1-|E \exp (i Z)|^{2}
$$

for any r.v. $Z$ and an independent copy, say $Z^{*}$, as well as condition A.2-SM with $\|t\|=\alpha$ we get

$$
E V_{j}^{2} \geq 1-\exp (-2 \alpha)
$$

which concludes the proof of equation 4, as all bounds are independent of $\theta$.
Hence, the following corollary.
Corollary 2.3 Under assumption A.2 conditions (2.2)-(2.6) of Gotze and Hipp [8] hold with constants independent of $\theta$.

Proof of Corollary 2.3. By assumption A.2 conditions (2.2), (2.4), (2.5) and (2.6) of Gotze and Hipp [8] obviously hold with constants independent of $\theta$. Condition of (2.3) of Gotze and Hipp [8] follows from lemma 2.2.

Now we need to show how the uniform versions of conditions (2.2)-(2.6) of Gotze and Hipp [8] imply intermediate results that lead to the proof of theorem 2.1. Again these are uniform extensions of the analogous results in Gotze and Hipp [8]. We shall employ the following notation. Define

$$
T(x)=\left\{\begin{array}{c}
x \quad \text { if }\|x\| \leq n^{\beta} \\
\frac{x n^{\beta}}{\|x\|} \psi\left(\|x\| n^{-\beta}\right) \quad \text { otherwise }
\end{array}\right.
$$

where $\psi \in C^{\infty}(0, \infty)$ independent of $\theta$, satisfying

$$
\begin{array}{ll}
\psi(r)=r \quad \text { if } r \leq 1 \\
& \psi \quad \text { is increasing } \\
\psi(r)=2 \quad \text { if } r \geq 2 .
\end{array}
$$

For $j=1, \ldots, n$ let $Y_{j}=T\left(X_{j}\right)$ and $Z_{j}^{*}=Y_{j}-E\left(Z_{j}\right)$. Define $S_{n}^{*}=$ $n^{-1 / 2}\left(Z_{1}^{*}+\ldots+Z_{n}^{*}\right)$ and $H_{n}(t)=E \exp \left(i t^{T} S_{n}^{*}\right)$. Notice that $\widetilde{P}_{r, n}, Y_{j}, Z_{j}^{*}$, $S_{n}^{*}$ and $H_{n}$ depend on $\theta$.

Let

$$
E_{t} U=E U \exp \left(i t^{T} S_{n}^{*}\right) / H_{n}(t)
$$

and define the cumulant of order $p$

$$
\kappa_{t}\left(a_{1}^{T} S_{n}^{*}, \ldots, a_{p}^{T} S_{n}^{*}\right)=\left.\frac{\partial}{\partial \varepsilon_{1}} \ldots \frac{\partial}{\partial \varepsilon_{p}}\right|_{\varepsilon_{1}=\ldots=\varepsilon_{p}=0} \ln H_{n}\left(t+\varepsilon_{1} a_{1}+. .+\varepsilon_{p} a_{p}\right),
$$

where $a_{1}, \ldots, a_{p} \in \mathbb{R}^{k}$. Write

$$
\kappa_{t}(\underbrace{a^{T} S_{n}^{*}, \ldots, a^{T} S_{n}^{*}}_{j-\text { times }}, \underbrace{T}_{l-\text { times }} S_{n}^{*}, \ldots, b^{T} S_{n}^{*})=\kappa_{t}\left(a^{T} S_{n}^{* j}, b^{T} S_{n}^{* l}\right),
$$

the Taylor expansion of $\ln H_{n}(t)$ can be written

$$
\begin{align*}
\ln H_{n}(t) & =\sum_{r=2}^{s} \frac{1}{r!} \kappa_{0}\left(i t^{T} S_{n}^{* r}\right)+R_{s+1}(t) \quad \text { where }  \tag{5}\\
R_{s+1}(t) & =\frac{1}{s!} \int_{0}^{1}(1-\eta)^{s} \kappa_{\eta t}\left(i t^{T} S_{n}^{*(s+1)}\right) d \eta
\end{align*}
$$

In what follows $c(\bullet)$ stands for a constant depending on the arguments within the parentheses.

Lemma 2.4 Under assumption A.2 Lemma (3.33) of Gotze and Hipp [8] holds with constant $c$ independent of $\theta$, i.e. for every $t$ with $\|t\|<c^{*} n^{\bar{\varepsilon}}$, we have that

$$
\begin{aligned}
& \left|D^{a}\left(H_{n}(t)-\widehat{\Psi}_{n, s}(t)\right)\right| \\
\leq & c(r, K, s,|a|)\left(1+\beta_{s+1}\right)\left(1+\|t\|^{3(s-1)+|a|}\right) \exp \left(-c(\alpha)\|t\|^{2}\right) n^{-(s-2) / 2-\bar{\varepsilon}}
\end{aligned}
$$

for $c^{*}>0,0<\bar{\varepsilon}<1 / 2$ and $c(r, K, s,|a|)$ a constant depending on $r, K, s$ and $|a|$ but not on $\theta$.

Proof of Lemma 2.4. (For analytic proof see Arvanitis and Demos [2]) Naturally, we follow closely the proof of Lemma (3.33) of Gotze and Hipp [8]. From Lemma (3.28) of Gotze and Hipp [8] we have that for $2 \leq r \leq s$

$$
\left|\kappa_{0}\left(a_{1}^{T} S_{n}^{*}, \ldots, a_{r}^{T} S_{n}^{*}\right)\right| \leq c(r, K, s) n^{-(r-2) / 2} \beta_{s+1}^{r /(s+1)}\left\|a_{1}\right\| \ldots\left\|a_{r}\right\|
$$

where $c$ depends on $r$ and $d$ but not on $\theta$. Now for $\|t\| \leq c^{*} n^{\varepsilon}$ we have that

$$
\left|D^{a} \sum_{r=3}^{s} \frac{\kappa_{0}\left(i t^{T} S_{n}^{* r}\right)}{r!}\right|=\left\{\begin{array}{cc}
1 & \text { for } s \leq|a| \\
n^{-(|a|-2) / 2} & \text { for } 3 \leq|a|<s \\
n^{-1 / 2}\|t\|^{3-|a|} & \text { for }|a|<3
\end{array} .\right.
$$

Now employing equation (5) we get

$$
\begin{aligned}
\Delta & =D^{a}\left(H_{n}(t)-\exp \left[\sum_{r=3}^{s} \frac{\kappa_{0}\left(i t^{T} S_{n}^{* r}\right)}{r!}\right]\right) \\
& =\sum_{a_{1}+a_{2}=a} c_{a_{1} a_{2}} D^{a_{1}} \exp \left[\sum_{r=3}^{s} \frac{\kappa_{0}\left(i t^{T} S_{n}^{* r}\right)}{r!}\right] D^{a_{2}}\left(\exp \left[R_{s+1}(t)\right]-1\right),
\end{aligned}
$$

where $c_{a_{1} a_{2}}$ are combinatorial coefficients. From Lemma (3.20) of Gotze and Hipp [8] we have that

$$
\left|\frac{\partial^{l}}{\partial \varepsilon^{l}}\right|_{\varepsilon=0} R_{s+1}(t+\varepsilon b) \left\lvert\, \leq c(r, K)\left(1+\beta_{s+1}\right) n^{-\frac{s-2}{2}-\varepsilon^{*}}\left(1+\theta_{n}(t)^{s+1+l}\right)\left(1+\|t\|^{s+1}\right)\right.
$$

where $0<\varepsilon^{*}<1, c(r, K)$ depends on $r$ and $K$ and for every $t$ satisfying

$$
\begin{equation*}
\theta_{n}(t)=\frac{v_{m}^{(n)}(t)+\exp \left(-c(\alpha) n^{\varepsilon^{*} / 2}\right)}{H_{n}(t)}<\infty, \quad\|t\| \leq \varepsilon^{*} n^{-\varepsilon^{*}-\beta+1 / 2} \tag{6}
\end{equation*}
$$

where $b \in \mathbb{R}^{k}$ with $\|b\|<1$ and

$$
v_{m}^{(n)}(t)=\sup \left\{\left|E \exp \left(S_{I}^{(p)}\right)\right|: p \leq m,|I| \leq r\right\}
$$

where $l$ such that $s+1 \leq r \leq s+1+l, S_{I}^{(p)}=i n^{-1 / 2} t^{T} \sum^{*} Z_{j}$ and $\sum^{*}$ extends over all $1 \leq j \leq n$ such that $\left|j-j_{1}\right|>m r$. Hence we get that

$$
|\Delta| \leq c(r, K)\left(1+\|t\|^{|a|}\right)\|t\|^{s+1}\left(1+\beta_{s+1}\right) n^{-(s-1) / 2-\varepsilon^{*}} \exp \left(-c^{*}\|t\|^{2}\right)\left(1+\theta_{n}(t)^{|a|}\right) .
$$

Now for complex $a_{i} \in \mathbb{C}^{k}$ with $\left\|\operatorname{Im} a_{i}\right\|<\eta$ and Lemma (3.30) of Gotze and Hipp [8] we have that

$$
\begin{align*}
& \left|\kappa_{0}\left(a_{1}^{T} S_{n}^{*}, \ldots, a_{r}^{T} S_{n}^{*}\right)-\kappa_{0}\left(a_{1}^{T} S_{n}, \ldots, a_{r}^{T} S_{n}\right)\right|  \tag{7}\\
\leq & c(r) n^{-(s-2) / 2-\varepsilon^{* *}} \beta_{s+1}^{r /(s+1)}\left\|a_{1}\right\| \ldots\left\|a_{r}\right\|, \quad \text { for } 1 \leq r \leq s \text { and } 0<\varepsilon^{* *}<1
\end{align*}
$$

Hence we have that

$$
\begin{aligned}
\exp \left(\sum_{r=2}^{s} \kappa_{0}\left(\frac{i}{r!} t^{T} S_{n}^{* r}\right)\right) & =\exp \left[o\left(n^{-(s-1) / 2+\varepsilon^{* *}}\|t\|\right)\right]\left(\widehat{\Psi}_{n, s}(t)+\bar{R}_{s}(t)\right) \\
& =\widehat{\Psi}_{n, s}(t)+\widetilde{R}_{s}(t)
\end{aligned}
$$

where
$\bar{R}_{s}(t) \leq c(r, K, s) n^{-(s-1) / 2}\left(1+\beta_{s+1}\right)\left(\|t\|^{s+1}+\|t\|^{3(s-1)}\right) \exp \left(-c_{2}\|\operatorname{Re} t\|^{2}+c_{3} \eta^{2}\right)$
Since $\widehat{\Psi}_{n, s}(t)$ and $\widetilde{R}_{s}(t)$ are analytic in $t$, the Cauchy's inequalities can be employed to estimate the derivatives $D^{a} \widetilde{R}_{s}(t)$. Noting that due to assumption A.2 and remark R.1 $\left|\widehat{\Psi}_{n, s}(t)\right| \leq c \exp \left(-c\|\operatorname{Re}(t)\|^{2}\right)$, for some $c>0$ independent of $\theta,\|\operatorname{Im}(t)\| \leq \eta$ and $\|\operatorname{Re}(t)\| \leq c^{*} n^{\varepsilon^{* *}}$ we get

$$
\left|D^{a} \widetilde{R}_{s}(t)\right| \leq c(r, K, s) n^{-(s-2) / 2-\varepsilon^{* *}}\left(1+\|t\|^{3(s-1)}\right) \exp \left(-c^{*}\|t\|^{2}\right)
$$

for every $t \in \mathbb{R}^{k}$ with $\|t\| \leq c^{*} n^{\varepsilon^{* *}}$. Hence

$$
\begin{aligned}
& \left|D^{a}\left(H_{n}(t)-\widehat{\Psi}_{n, s}(t)\right)\right| \\
\leq & c(r, K, s)\left(1+\beta_{s+1}\right)\left(1+\|t\|^{3(s-1)+|a|}\right)\left(1+\theta_{n}(t)^{|a|+1}\right) \exp \left(-c^{*}\|t\|^{2}\right) n^{-(s-2) / 2-\bar{\varepsilon}}
\end{aligned}
$$

Now for $\theta_{n}(t)$ in equation 6, let $T_{l}=n^{-1 / 2} \sum_{p=1}^{l} Z_{j_{p}}$, for $1 \leq l \leq n$ for any sequence $j_{1} \leq j_{2} \leq \ldots \leq j_{l}$ and define $H\left(T_{l}, t\right)=E \exp \left(i t^{T} T_{l}\right)$. Now equation 5, Lemma (3.20) and Lemma (3.28) of Gotze and Hipp [8] can be employed together to prove that for $1 \leq l \leq n$ and $a=0$ :

$$
H\left(T_{l}, t\right)=\exp \left[-\frac{1}{2} \kappa_{0}\left(t^{T} T_{l}^{2}+c^{*} n^{-3 / 2-\bar{\varepsilon}}\|t\|^{3} l \theta_{l, 3}(t)\right)\right]
$$

where
$\left|\theta_{l, 3}(t)\right| \leq \sup \left\{\left|\left(\exp \left(-c^{*} n^{\varepsilon}\right)+H\left(T_{I, l}^{(p)}, t\right)\right) / H\left(T_{l}, t\right)\right|^{3}:|I| \leq 3,0 \leq p \leq m, T_{l}\right\}$
where $T_{I, l}^{(p)}=i n^{-1 / 2} t^{T} \sum^{*} Z_{j}$ where $\sum^{*}$ extends over all $1 \leq j \leq l$ such that $\left|j-j_{1}\right|>p m$ for every $j_{1} \in I \subset\{1,2, \ldots, l\}$. Notice that here $\varepsilon, c^{*}$ and $m$ are independent of $l, 1 \leq l \leq n$. The claim is that

$$
\begin{equation*}
\sup \left\{\left|\theta_{l, 3}(t)\right|:\|t\| \leq n^{\bar{\varepsilon}}\right\} \leq 2 \quad \text { for } l=1,2, \ldots, n \tag{8}
\end{equation*}
$$

provided that $n$ is sufficiently large (depending on $s, k, d, \beta_{s+1}$ ) but not on $\theta$. For $l=1$ the above inequality holds trivially and the proof follows by induction as in Gotze and Hipp [8] (see Arvanitis and Demos [2] for analytic proof, as well).

Lemma 2.5 Under the assumptions of the previous lemma, (3.3) of Gotze and Hipp [8] holds with constant $c$ and $o\left(n^{\frac{s-2+\delta}{2}}\right)$ independent of $\theta$, i.e. for $f: \mathbb{R}^{k} \rightarrow \mathbb{R}$ such that $|f(x)| \leq M\left(1+\|x\|^{s_{0}}\right)$ for every $x \in \mathbb{R}^{k}$ and $M$ independent of $\theta$. Then for $\kappa>0$

$$
\begin{aligned}
& \sup _{\theta \in \Theta}\left|E f\left(S_{n}\right)-\int f d \Psi_{n, s}\right| \\
\leq & c\left(k, s, \beta_{s+1}\right) M \sup _{|\alpha| \leq k+1+s_{0}} \sup _{\theta \in \Theta} \int\left|D^{\alpha}\left[\left(H_{n}(t)-\widehat{\Psi}_{n, s}(t)\right) \widehat{K}\left(n^{-\kappa} t\right) \exp \left(i t^{T} e_{n}\right)\right]\right| d t \\
& +c\left(k, s, \beta_{s+1}\right) \sup _{\theta \in \Theta} \omega\left(g: n^{-\kappa}\right)+o\left(n^{-\frac{s-2+\delta}{2}}\right)
\end{aligned}
$$

where

$$
\begin{aligned}
\delta & >0, g(x)=f(x) /\left(1+\|x\|^{s_{0}}\right) \\
\omega\left(g: n^{-\kappa}\right) & =\int \sup \left\{|g(x+y)-g(x)|:\|y\| \leq n^{-\kappa}\right\} \Phi_{\Sigma_{n}}(d x), \\
\Sigma_{n} & =\operatorname{var}\left(S_{n}\right)
\end{aligned}
$$

and $\widehat{K}$ is a continuous function with compact support independent of $\theta$.
Proof of Lemma 2.5. Following the proof in Gotze and Hipp [8, define $S_{n}^{\prime}=n^{-1 / 2} \sum_{1}^{n} Y_{j}$ and letting $\bar{\varepsilon}>0$, to be defined later, define

$$
A=\left\{\sup _{\theta \in \Theta}\left\|S_{n}\right\| \leq n^{\varepsilon}\right\}, \quad B=\left\{\sup _{\theta \in \Theta}\left\|S_{n}^{\prime}\right\| \leq n^{\varepsilon}\right\} .
$$

Then employing that $(x+y)^{n} \leq 2^{n}\left(x^{n}+y^{n}\right), n, x, y>0$ we get

$$
\begin{aligned}
& \sup _{\theta \in \Theta} E\left\|S_{n}-S_{n}^{\prime}\right\|^{s_{0}} \\
\leq & c(s)\left(\sup _{\theta \in \Theta} E\left\|S_{n}\right\|^{s_{0}} 1_{A^{c}}+\sup _{\theta \in \Theta} E\left\|S_{n}\right\|^{s_{0}} 1_{B^{c}}+n^{\bar{\varepsilon} s_{0}} \sup _{\theta \in \Theta} P\left\{S_{n} \neq S_{n}^{/}\right\}\right) .
\end{aligned}
$$

Furthermore, due to equation 7 we have that there exists $0<\delta$ independent of $\theta$, such that

$$
\begin{aligned}
& \sup _{\theta \in \Theta} E\left\|S_{n}\right\|^{s_{0}} 1_{A^{c}} \\
\leq & c\left(s, \beta_{s+1}\right) o\left(n^{-(s-2+\delta) / 2}\right)+2 n^{\bar{\varepsilon} s_{0}} \sup _{\theta \in \Theta} P\left\{S_{n} \neq S_{n}^{\prime}\right\}+\sup _{\theta \in \Theta} E\left\|S_{n}\right\|^{s_{0}} 1_{B^{c}}
\end{aligned}
$$

and consequently,

$$
\begin{aligned}
& E\left\|S_{n}-S_{n}^{\prime}\right\|^{s_{0}} \\
\leq & c\left(s, \beta_{s+1}\right)\left(\sup _{\theta \in \Theta} E\left\|S_{n}^{\prime}\right\|^{s_{0}} 1_{B^{c}}+n^{\overline{s_{s}}} \sup _{\theta \in \Theta} P\left\{S_{n} \neq S_{n}^{\prime}\right\}\right)+o\left(n^{-(s-2+\delta) / 2}\right) .
\end{aligned}
$$

Now Lemma 2.4 imply that for arbitrary positive integer $r$ we have that $\sup _{\theta \in \Theta} \sup _{n} E\left\|S_{n}^{\prime}\right\|^{r}<\infty$ and consequently for $\bar{\varepsilon}$ such that

$$
0<\bar{\varepsilon}<(s+1) \beta_{s+1}-(s-2) / 2
$$

-hence, independent of $\theta$-we get that

$$
E\left\|S_{n}-S_{n}^{\prime}\right\|^{s_{0}} \leq c\left(s, \beta_{s+1}\right) o\left(n^{-(s-2) / 2}\right) .
$$

This along with the definition of $f$ imply that

$$
\left|E f\left(S_{n}\right)-E f\left(S_{n}^{\prime}\right)\right| \leq c\left(s, \beta_{s+1}\right) o\left(n^{-(s-2) / 2}\right) .
$$

Notice that for

$$
e_{n}=O\left(n^{1 / 2} n^{-s \beta_{s+1}}\right)=o\left(n^{-(s-2+\delta) / 2}\right)
$$

which is independent of $\theta$ and

$$
\sup _{\theta \in \Theta}\left|\int f\left(\bullet, e_{n}\right) d \Psi_{n, s}-\int f d \Psi_{n, s}\right|=o\left(n^{-(s-2+\delta) / 2}\right) .
$$

Now from Lemma 11.6 in Bhattacharya and Rao [4], by applying the Sweeting Smoothing Inequality (Lemma 5 of [15]) and by noting that this inequality involves constants that depend solely on the properties of $g$ and therefore are independent of $\theta$ along with a similar choice of $\widehat{K}$ we get the result.

We are now ready to prove theorem 2.1.
Proof of Theorem 2.1. Consider the functions $f$ and $g$ as defined in lemma 2.5. Then, from lemma 2.4 and lemma 2.5 and for $\kappa=(s-2+\delta) / 2$ we obtain that
$\left|E f\left(S_{n}\right)-\int f d \Psi_{n, s}\right| \leq c\left(k, s, \beta_{s+1}\right) \sup _{\theta \in \Theta} \omega\left(g: n^{-(s-2+\delta) / 2}\right)+M c\left(k, s, \beta_{s+1}\right) o\left(n^{-\frac{s-2+\delta}{2}}\right)$
Now for $f(x)=1_{C}(x)\left(1+\|x\|^{s_{0}}\right) \cdot \mid$ where $C \in \mathcal{B}_{C}$, and $1_{C}(x)$ is its indicator function we have that

$$
\sup _{y \leq n^{-k}}\left|1_{C}(x+y)-1_{C}(x)\right| \leq 1_{(\partial C)^{n^{-k}}}(x)
$$

[^0]for large enough $n$ (where $\partial$ is the boundary operator and the superscript .$n^{-k}$ denotes the analogous enlargement), hence
\[

$$
\begin{aligned}
& \sup _{\theta \in \Theta} \omega\left(g: n^{-(s-2+\delta) / 2}\right) \\
= & \sup _{\theta \in \Theta} \int \sup _{y}\left\{|g(x+y)-g(x)|:\|y\| \leq n^{-(s-2+\delta) / 2}\right\} \Phi_{\Sigma_{n}}(d x) \\
\leq & \sup _{\theta \in \Theta} \int 1_{(\partial C)^{n^{-(s-2+\delta) / 2}}}(x) \Phi_{\Sigma_{n}}(d x)=\sup _{\theta \in \Theta} \int 1_{\Sigma_{n}^{-1 / 2}(\partial C)^{n^{-(s-2+\delta) / 2}}}(x) \Phi(d x)
\end{aligned}
$$
\]

and due to remark R. 1 for $\Sigma^{*}$ the diagonal matrix with elements consisting of the inverse of $\inf _{\theta \in \Theta} \liminf \inf _{n} \sqrt{\lambda_{n}^{\min }(\theta)}$, due to the fact that $\partial$ and enlargement commutes with $\Sigma^{*}$, the linear transformation of a convex set is convex the we have that the last term is less than or equal to

$$
\int 1_{\left(\partial\left(\Sigma^{*} C\right)\right)^{n^{-(s-2+\delta) / 2}}}(x) \Phi(d x)=o\left(n^{-(s-2) / 2}\right)
$$

due to Corollary 3.2 of Bhattacharya and Rao [4].

### 2.1 Sufficient Conditions For Smoothness

In this paragraph we provide uniform versions of conditions 2.3.(i)-(iii) of Gotze and Hipp [9] and prove that they imply assumption A.2-SM in the case that $X_{j}$ in assumption A. 1 is represented as

$$
\begin{equation*}
X_{j}=g\left(\varepsilon_{j-i}: i \in \mathbb{Z}, \theta\right), \quad j \in \mathbb{Z} \tag{9}
\end{equation*}
$$

(obviously $g$ in the current representation could be the composition of $h(\cdot, \theta)$ with $g(\cdot, \theta)$ in the language of assumption A.1). Again the proof of sufficiency traces the arguments in the proof of Lemma 2.3 of Gotze and Hipp [9], establishing that the analogous bounds can be chosen independent of $\theta$. Again we employ the auxiliary notation of the aforementioned paper as well as extend to uniform versions the auxiliary results. Hence, for $j \in \mathbb{Z}$ and $y \in \mathbb{R}^{\mathbb{Z}}, x \in \mathbb{R}$ let $(y, x)^{j}$ be the sequence with coordinates

$$
\left\{\begin{array}{cc}
y_{i}, & i<j \\
x, & i=j \\
y_{i-1} & i>j .
\end{array}\right.
$$

Consider the following assumption.

Assumption A. 3 Let the following conditions hold:
-EL There exist $K<\infty$, and $\alpha>0$, not depending on $\theta$, such that,

$$
\sup _{\theta \in \Theta} \sum_{j=0}^{\infty} E\left(\left\|\frac{\partial}{\partial \varepsilon_{0}} X_{j}\right\|\right)<\frac{2 K}{1-\exp (-\alpha)}
$$

-CPD (Almost sure continuity of partial derivatives) For $j \in \mathbb{Z}$ there exists $G_{j} \subset \mathbb{R}, P\left(G_{j}\right)=1$ independent of $\theta$, such that for all $x_{0} \in G_{j}, \eta$, $\delta>0$ there exists $\tau>0$ independent of $\theta$ satisfying
$P\left\{\begin{array}{c}y \in \mathbb{R}^{\mathbb{Z}}: \forall x \in \mathbb{R},\left|x-x_{0}\right|<\tau, \frac{\partial}{\partial \varepsilon_{0}} X_{j} \text { exists at the point }(y, x)^{j} \text { and } \\ \sup _{\theta \in \Theta}\left|\frac{\partial}{\partial \varepsilon_{0}} X_{j}\left((y, x)^{j}, \theta\right)-\frac{\partial}{\partial \varepsilon_{0}} X_{j}\left(\left(y, x_{0}\right)^{j}, \theta\right)\right| \leq \delta\end{array}\right\} \geq 1-\eta$
-NDD (Non-degenerate derivatives on a set of positive probability) For some distinct $l_{1}, \ldots l_{k} \geq 0$ independent of $\theta$,

$$
\inf _{\theta \in \Theta} \operatorname{det}\left(\sum_{j=0}^{\infty} \frac{\partial}{\partial \varepsilon_{l_{\nu}}} X_{j}: \nu=1, \ldots, k\right) \neq 0
$$

on a set of positive $P$-probability independent of $\theta$.
Notice that assumption A.3-EL is weaker than the condition 2.3.(i) in page 2073 of Gotze and Hipp [9. In fact in our example, although the aforementioned condition does not hold, assumption A.3-EL applies. The required result is the following.

Lemma 2.6 Under equation 9, assumption A.3 and if $\varepsilon_{j}$ admits a positive continuous density, then assumption A.2-SM holds for the sequence $\left(X_{j}\right)$, $j \in \mathbb{Z}$.

For its proof, we shall need the following lemma which is the uniform extension of Lemma 2.2 of Gotze and Hipp [9].
Lemma 2.7 Let $\mathcal{O}_{r} \subset \mathbb{R}^{k}$ denote an open ball with radius $r$ and let $F$ : $\mathbb{R}^{k} \times \Theta \rightarrow \mathbb{R}^{k}$ denote a measurable function that is injective and continuously differentiable function on $\mathcal{O}_{r}$ w.r.t. the first argument for any $\theta \in \Theta$, such that for constants $\eta>0$ and $M<\infty$ that do not depend on $\theta$ and for all $x \in O$,

$$
\eta \leq\left|\operatorname{det} F^{\prime}(x, \theta)\right| \leq M \text { and }\left\|F^{\prime}(x, \theta)\right\| \leq M .
$$

where $F^{\prime}$ denotes the aforementioned derivative. Let $h$ denote a density on $\mathbb{R}^{k}$ satisfying $h(x) \geq \eta, x \in \mathcal{O}_{r}$, and fix $\delta>0$. Then there exists $\rho<1$ depending only on $\eta, \delta, M$ and $r$ such that for $t \in \mathbb{R}^{k}$ with $\|t\| \geq \delta$,

$$
\sup _{\theta \in \Theta}\left|\int \exp \left[i t^{T} F(x, \theta)\right] h(x) d x\right| \leq \rho(k, \delta, M, r) .
$$

Proof of Lemma 2.7. For this proof, $\rho(\bullet)$ is a constant depending on the arguments within the parentheses. Following the proof in Gotze and Hipp 9 (see Arvanitis and Demos 2 for analytic proof), by a change of variables and noticing that for $x \in O$ we have that $\inf _{\theta \in \Theta} \frac{h(x)}{|\operatorname{det} F /(x, \theta)|} \geq \frac{\eta}{M}$ we have that

$$
\left|\int_{F_{\theta}\left(\mathcal{O}_{r}\right)} \exp \left[i t^{T} u\right]\left(\frac{h\left(F_{\theta}^{-1}(u)\right)}{\left|\operatorname{det} F^{\prime}\left(F_{\theta}^{-1}(u), \theta\right)\right|}-\frac{\eta}{M}\right) d u\right| \leq \int_{\mathcal{O}_{r}} h(x) d x-\int_{F_{\theta}\left(\mathcal{O}_{r}\right)} \frac{\eta}{M} d u .
$$

Fix $1 \leq j \leq k$ and $u_{1}, \ldots, u_{j-1}, u_{j+1}, \ldots, u_{k}$. Then $\left\{u_{j}:\left(u_{1}, \ldots, u_{k}\right) \in F_{\theta}\left(\mathcal{O}_{r}\right)\right\}$ is an interval with endpoints, say, $a(\theta)<b(\theta)$ and $\left|\int_{a(\theta)}^{b(\theta)} \exp \left[i t^{T} u\right] d u_{j}\right| \leq$ $\frac{2}{\left|t_{j}\right|}$. Let $A(\theta)=\left\{\left(u_{1}, \ldots, u_{j-1}, u_{j+1}, \ldots, u_{k}\right): \exists u_{j} \in \mathbb{R}:\left(u_{1}, \ldots, u_{k}\right) \in F_{\theta}\left(\mathcal{O}_{r}\right)\right\}$, and since $A(\theta)$ is the projection of $F_{\theta}\left(\mathcal{O}_{r}\right)$ onto $\mathbb{R}^{k-1}$ and $F_{\theta}\left(\mathcal{O}_{r}\right)$ is contained in a ball of radius $M r$, we get that

$$
\left|\int_{F_{\theta}\left(\mathcal{O}_{r}\right)} \exp \left[i t^{T} u\right] d u\right| \leq \frac{2}{\left|t_{j}\right|}(2 M r)^{k-1} .
$$

Since $1 \leq j \leq k$ was arbitrary, we can find $\xi>0$ depending on $k, \eta, M$ and $r$ only such that for $t \in \mathbb{R}^{k}$ and $\|t\| \geq \xi$,

$$
\left|\int_{F_{\theta}\left(\mathcal{O}_{r}\right)} \exp \left[i t^{T} u\right] d u\right| \leq \frac{1}{2} \int_{F_{\theta}\left(\mathcal{O}_{r}\right)} d x .
$$

Hence for these $t$,

$$
\begin{aligned}
& \left|\int \exp \left[i t^{T} F(x, \theta)\right] h(x) d x\right| \\
\leq & \int_{\mathcal{O}_{r}^{c}} h(x) d x+\int_{\mathcal{O}_{r}} h(x) d x-\frac{\eta}{M} \int_{F_{\theta}\left(\mathcal{O}_{r}\right)} d x+\frac{\eta}{2 M} \int_{F_{\theta}\left(\mathcal{O}_{r}\right)} d x \\
= & 1-\frac{\eta}{2 M} \int_{F_{\theta}\left(\mathcal{O}_{r}\right)} d x \leq 1-\frac{\eta^{2}}{2 M} \int_{\mathcal{O}_{r}} d x=1-\frac{\eta^{2}}{2 M} \frac{\pi^{k / 2} r^{k}}{\Gamma\left(\frac{k}{2}+1\right)}=\rho(k, \eta, M, r) .
\end{aligned}
$$

We are now ready to prove lemma 2.6
Proof of Lemma 2.6. Following closely the proof in Gotze and Hipp [9], by assumption A.3-NDD we can find a number $\eta>0$ and a set $A$ of sequences $y \in \mathbb{R}^{\mathbb{Z}}$, independent of $\theta$, with $P(A)>0$ such that for $y \in A$ the partial derivatives $\frac{\partial}{\partial \varepsilon_{0}} X_{j}, j \in \mathbb{Z}$, are defined at $y$, and

$$
\inf _{\theta \in \Theta} \operatorname{det}\left|\left(\sum_{j=0}^{\infty} \frac{\partial}{\partial \varepsilon_{l_{\nu}}} X_{j}: \nu=1, \ldots, k\right)\right| \geq \eta .
$$

Let $\|B\|=\sup \{\|B x\|:\|x\| \leq 1\}$ for any $k \times k$ matrix $B$ and let $c(k)$ denote a universal constant satisfying

$$
\left|\operatorname{det} B_{1}-\operatorname{det} B_{2}\right| \leq c(k)\left(\left\|B_{1}\right\|^{k-1}+\left\|B_{2}\right\|^{k-1}\right)\left\|B_{1}-B_{2}\right\|
$$

for arbitrary $k \times k$ matrices $B_{1}$ and $B_{2}$. From assumption A.3-EL we get that

$$
\begin{equation*}
\sup _{\theta \in \Theta} \sum_{j=0}^{\infty} E\left(\left\|\frac{\partial}{\partial \varepsilon_{0}} X_{j}(y)\right\| 1_{A}(y)\right)<\frac{2 K}{1-\exp (-\alpha)} \tag{10}
\end{equation*}
$$

It follows that there exists a measurable subset $A^{\prime} \subset A$, independent of $\theta$, with $P\left(A^{\prime}\right)>0$ and $m_{0}>0$ such that for $y \in A^{\prime}$,

$$
\sup _{\theta \in \Theta}\left\|\sum_{j=m_{0}+1}^{\infty} \frac{\partial}{\partial \varepsilon_{l_{\nu}}} X_{j}(y): \nu=1, \ldots, k\right\| \leq \frac{\eta}{4 C(k, K, \alpha)}
$$

where $C(k, K, \alpha)=2 C(k)\left(\frac{2 K}{1-\exp (-\alpha)}\right)^{k}$. Further estimating the difference of determinants for all $y \in A^{\prime}$ we get

$$
\begin{equation*}
\sup _{\theta \in \Theta}\left|\operatorname{det}\left(\sum_{j=0}^{m_{0}} \frac{\partial}{\partial \varepsilon_{l_{\nu}}} X_{j}(y): \nu=1, \ldots, k\right)\right| \leq \frac{3 \eta}{4} . \tag{11}
\end{equation*}
$$

For $y \in \mathbb{R}^{\mathbb{Z}}$ and $x=\left(x_{1}, \ldots, x_{k}\right)$ let $(y, x)$ be the sequence, such that for $\nu=1, \ldots, k, x_{\nu}$ is inserted at place $l_{\nu}$ and all other places are filled with the components of $y$ :

$$
(y, x)_{j}=\left\{\begin{array}{cc}
x_{j}, \quad \text { if } j \in\left\{l_{1}, \ldots, l_{k}\right\}, \\
y_{j-i}, & \text { if } i=1, \ldots, k \text { and } l_{i-1}<j<l_{i+1} .
\end{array}\right.
$$

Here $l_{0}=-\infty$ and $l_{k+1}=+\infty$. For $x \in \mathbb{R}^{k}$ let

$$
A(x)=\left\{y \in \mathbb{R}^{\mathbb{Z}}:(y, x) \in A\right\} .
$$

Since $P(A)>0$, we can find $x^{(0)} \in G_{l_{1}} \times \ldots \times G_{l_{k}}$ such that $P\left(A\left(x^{(0)}\right)\right)>0$. Assumption A.3-CPD implies that for $\delta>0$ there exists a small ball $B \subset \mathbb{R}^{k}$ containing $x^{(0)}$ and a set $A^{/ /} \subset A^{\prime}$ with $P\left(A^{/ /}\right)>0$ such that for $y \in A^{/ /}$ and $x \in B$ and for $\nu=1, \ldots, k$ and $j=0, \ldots, m_{0}, \frac{\partial}{\partial \epsilon_{l_{\nu}}} X_{j}$ exists at $(y, x)$ for all $\theta \in \Theta$ and

$$
\sup _{\theta \in \Theta}\left\|\frac{\partial}{\partial \varepsilon_{l_{\nu}}} X_{j}\left(\left(y, x^{(0)}\right), \theta\right)-\frac{\partial}{\partial \varepsilon_{l_{\nu}}} X_{j}((y, x), \theta)\right\| \leq \delta .
$$

Choosing appropriately small $\delta$, we obtain (estimating the change of determinants) from this and equation $11, x \in B$ and $y \in A^{/ /}$,

$$
\inf _{\theta \in \Theta}\left|\operatorname{det}\left(\sum_{j=0}^{m_{0}} \frac{\partial}{\partial \varepsilon_{l_{\nu}}} X_{j}((y, x), \theta): \nu=1, \ldots, k\right)\right| \geq \frac{\eta}{2} .
$$

This implies that for $m \geq m_{0}$ and $x \in B, y \in A^{/ /}$we have by equation 10 again estimating the change of determinants

$$
\inf _{\theta \in \Theta}\left|\operatorname{det}\left(\sum_{j=0}^{m} \frac{\partial}{\partial \varepsilon_{l_{\nu}}} X_{j}((y, x), \theta): \nu=1, \ldots, k\right)\right| \geq \frac{\eta}{4} .
$$

By lemma 2.7 we get that for $\delta>0$ there exists $\rho<1$ depending only on $\delta, \eta$ and $B$ (not on $m$ and $\theta$ ) such that for $m>m_{0}$ and all $y \in A^{/ /}$and $\|t\| \geq \delta$,

$$
\sup _{\theta \in \Theta}\left|\int_{B} \exp \left[i t^{T}\left(X_{0}+\ldots+X_{m}\right)\right] \prod_{\nu=1}^{k} h\left(\varepsilon_{l_{\nu}}\right) d \varepsilon_{l_{1}} \ldots d \varepsilon_{l_{k}}\right| \leq \rho(\delta, \eta, b)
$$

where $b$ is the radius of the ball $B$. Now the left-hand side is an upper bound for

$$
\left|E \left(\exp \left[i t^{T}\left(X_{0}+\ldots+X_{m}\right)\right]\left|\varepsilon_{j}:|j-m| \geq r\right) \mid\right.\right.
$$

where $r=\max \left(l_{1}, \ldots, l_{k}\right)$. This implies
$E\left|E\left(\exp \left[i t^{T}\left(X_{0}+\ldots+X_{m}\right)\right]\left|\varepsilon_{j}:|j-m| \geq r\right) \mid \leq 1-P\left(A^{/ /}\right)+\rho P\left(A^{/ /}\right)\right.\right.$, which proves the lemma.

## 3 Sequences of Smooth Transformations of Valid Locally Uniform Edgeworth Expansions

We are now considering the question of whether appropriately smooth transformations of sequences of random elements, with distributions that admit locally uniform Edgeworth expansions as the one described in equation 2, admit analogous expansions. In this section we follow the line of reasoning of Skovgaard [14]. We suppose that $\left(S_{n}(\theta)\right)_{n}$ is a sequence of random elements not necessarily of the form described immediately after assumption A.1. Furthermore the distribution of $S_{n}(\theta)$ admits a locally uniform Edgeworth expansion of order $s-2$, i.e. there exists some $\theta_{0}$ and $\varepsilon>0$ for which equation 2 holds for all $\theta \in \mathcal{O}\left(\theta_{0}, \varepsilon\right)$, where $\mathcal{O}\left(\theta_{0}, \varepsilon\right)$ denotes an open ball with centre $\theta_{0}$ and radius $\varepsilon$, with $\Psi_{n, s}(\theta)$ an Edgeworth distribution (not necessarily the formal one). ${ }^{2}$

[^1]Question Let $f_{n}: \mathbb{R}^{q} \rightarrow \mathbb{R}^{p}$. Find sufficient conditions for the validity of

$$
\begin{equation*}
\sup _{\theta \in \Theta} \sup _{A \in B_{c}^{*}}\left|P\left(f_{n}\left(S_{n}(\theta)\right) \in A\right)-\Psi_{n, s}^{*}(\theta)(A)\right|=o\left(n^{-\frac{s-2}{2}}\right) \tag{12}
\end{equation*}
$$

where $\Psi_{n, s}^{*}(\theta)$ is an Edgeworth distribution of order $s-2(s \geq 3)$ on $\mathbb{R}^{p}$ and $B_{c}^{*}$ is the collections of the convex Borel subsets of $\mathbb{R}^{p}$.

In section 4 we will utilize the forthcoming answer to this in order to establish locally uniform Edgeworth expansions of statistical functions of interest. We first make the following assumption.

Assumption A. 4 Let the following conditions hold:
-POL $f_{n}(x, \theta)=\sum_{i=0}^{s-2} \frac{A_{i_{n}}(\theta)\left(x^{i+1}\right)}{n^{i / 2}}$ where $A_{i_{n}}: \Theta \times \mathbb{R}^{q^{i+1}} \rightarrow \mathbb{R}^{p}$ is $(i+1)$ linear $\forall \theta \in \Theta, x^{i}=(\underbrace{x, \ldots, x}_{\text {i-times }}), A_{0_{n}}(\theta)=A_{0}(\theta), \operatorname{rank} A_{0}(\theta)=p \forall \theta \in \Theta$, $A_{i_{n}}$ equicontinuous on $\Theta, \forall x^{i+1}$.
-EEQ The $i^{\text {th }}$ polynomial, say, $\pi_{i}(z, \theta)$ of $\Psi_{n, s}(\theta)$ is equicontinuous on $\Theta$ $\forall z \in \mathbb{R}^{q}$, for $i=1, \ldots, s-2$, and if $\Sigma(\theta)$ denotes the variance matrix in the density of $\Psi_{n, s}(\theta)$ then it is continuous on $\Theta$ and positive definite.

Remark R. 2 Obviously assumption A.4-POL implies that $p \leq q$ while if $\Psi_{n, s}(\theta)$ is the formal Edgeworth distribution the required equicontinuity in A.4-EEQ would follow from the continuity of $E\left(K_{i}\left(S_{n}(\theta)\right)\right)$ on $\Theta$ for $i=$ $1, \ldots, s+1$ and $K_{i}$ any $i$-linear real function on $\mathbb{R}^{q^{i}}$, while lemma 2.2 equation 4 provides sufficient conditions for the validity of the eigenvalue condition in A.4-EEQ. Furthermore continuity and compactness imply that $\inf _{\theta \in \Theta} \lambda_{\text {min }}\left(A_{0}(\theta)\right), \inf _{\theta \in \Theta} \lambda_{\text {min }}(\Sigma(\theta))>0$ where $\lambda_{\text {min }}(\cdot)$ denotes the smallest absolute eigenvalue.

The following theorem provides the first result of this section.
Theorem 3.1 Under assumption A.4 there exist an Edgeworth distribution $\Psi_{n, s}^{*}(\theta)$ for which equation 12 is valid, with polynomials that satisfy A.4-EEQ. Furthermore, if $K$ is a m-linear real function on $\mathbb{R}^{p}$ then

$$
\sup _{\theta \in \Theta}\left|\int_{\mathbb{R}^{p}} K\left(x^{m}\right) d \Psi_{n, s}^{*}(\theta)-\int_{\mathbb{R}^{q}} K\left(\left(f_{n}(x)\right)^{m}\right) d \Psi_{n, s}(\theta)\right|=o\left(n^{\frac{s-2}{2}}\right)
$$

In order to prove the theorem we will utilize the following auxiliary results.

Lemma AL. 1 Suppose that $S_{n}$ admits an Edgeworth expansion of order s2. Then for any $i<j: 1, \ldots q, \operatorname{pr}_{i, j}\left(S_{n}\right) \doteqdot\left(S_{n_{i}}, S_{n_{i+1}}, \ldots, S_{n_{j}}\right)^{\prime}$ admits an analogous expansion of the same order.

Proof. The density of $\Psi_{n, s}(\theta)$ is of the form $\left(1+\sum_{i=1}^{s-2} \frac{1}{n^{\frac{2}{2}}} \pi_{i}(x, \theta)\right) \varphi_{\Sigma(\theta)}(x)$. For $A$ a convex Borel set in $\mathbb{R}^{j-i+1}$ we have

$$
\begin{aligned}
P\left(\operatorname{pr}_{i, j}\left(S_{n}(\theta)\right) \in A\right) & =P\left(S_{n}(\theta) \in \operatorname{pr}_{i, j}^{-1}(A)\right) \\
& =\int_{\mathbb{R} \times \ldots \times A \times \ldots \mathbb{R}}\left(1+\sum_{i=1}^{s-2} \frac{1}{n^{\frac{i}{2}}} \pi_{i}(x, \theta)\right) \varphi_{\Sigma(\theta)}(x) d x+o\left(n^{-\frac{s-2}{2}}\right) \\
& =\int_{A}\left(1+\sum_{i=1}^{s-2} \frac{1}{n^{\frac{i}{2}}} \pi_{i}^{*}(v, \theta)\right) \varphi_{I \Sigma(\theta) I^{\prime}} d v+o\left(n^{-\frac{s-2}{2}}\right)
\end{aligned}
$$

where $v=\operatorname{pr}_{i, j}(x), x=\left(v, v^{*}\right), I=\left(0, \operatorname{Id}_{j-i+1 \times j-i+1}, 0\right)$, and $\pi_{i}^{*}(v)=$ $\int_{\mathbb{R}^{q-p}} \pi_{i}\left(v, v^{*}, \theta\right) \varphi_{\Sigma(\theta)}\left(v, v^{*}\right) d v^{*}$ and $o\left(n^{-\frac{s-2}{2}}\right)$ is independent of $A$ and $\theta$.

Lemma AL. 2 Suppose that $S_{n}(\theta)$ admits a locally uniform Edgeworth expansion of order $s-2$ for which assumption A. $4-E E Q$ holds. Then there exists a constant $C$ independent of $\theta$ such that

$$
\sup _{\theta \in \Theta} P\left(\left\|S_{n}(\theta)\right\|>C \ln ^{1 / 2} n\right)=o\left(n^{\frac{s-2}{2}}\right)
$$

Proof. Let $C=\frac{\sqrt{s-1}}{\sup _{\theta \in \Theta}\left\|\Sigma^{-1 / 2}(\theta)\right\|}, \mathcal{H}_{n}(C)=\left\{x \in \mathbb{R}^{q}:\|x\|>C \ln ^{1 / 2} n\right\}$.
Then
$P\left(\left\|S_{n}(\theta)\right\|>C \ln ^{1 / 2} n\right)=\int_{\mathcal{H}_{n}(C)}\left(1+\sum_{i=1}^{s-2} \frac{1}{n^{\frac{i}{2}}} \pi_{i}(x, \theta)\right) \varphi_{\Sigma(\theta)}(x) d x+o\left(n^{-\frac{s-2}{2}}\right)$
where the last term on the right is independent of $\theta$. Now

$$
\begin{aligned}
& \left|\int_{\mathcal{H}_{n}(C)}\left(1+\sum_{i=1}^{s-2} \frac{1}{n^{\frac{i}{2}}} \pi_{i}(x, \theta)\right) \varphi_{\Sigma(\theta)}(x) d x\right| \\
\leq & \int_{\Sigma^{-1 / 2}(\theta) \mathcal{H}_{n}(C)}\left(1+\sum_{i=1}^{s-2} \frac{1}{n^{\frac{i}{2}}} \sup _{\theta \in \Theta}\left|\pi_{i}\left(\Sigma^{1 / 2}(\theta) z, \theta\right)\right|\right) \exp \left(-\frac{1}{2}\|z\|^{2}\right) d z \\
\leq & \int_{\mathcal{H}_{n}(1)}\left(1+\sum_{i=1}^{s-2} \frac{1}{n^{\frac{i}{2}}} \sup _{\theta \in \Theta}\left|\pi_{i}\left(\Sigma^{1 / 2}(\theta) z, \theta\right)\right|\right) \exp \left(-\frac{1}{2}\|z\|^{2}\right) d z
\end{aligned}
$$

Assumption A.4.EEQ (see also the last part of R.2) implies that $\sup _{\theta \in \Theta}\left|\pi_{i}\left(\Sigma^{1 / 2}(\theta) z, \theta\right)\right| \leq \sum_{i=1}^{m} c_{i}\|z\|^{i}$ for some finite $m$ and $c_{i} i=1, \ldots, m$ independent of $\theta$. The result follows from equation (A.8) in the proof of Lemma 2 in Magdalinos [11.

Lemma AL. 3 Let $f_{n}$ be as in assumption A.4-POL and $p=q$. Then there exists a function $h_{n}: \Theta \times \mathbb{R}^{p} \rightarrow \mathbb{R}^{p}$ of the form $h_{n}(x, \theta)=\sum_{i=0}^{s-2} \frac{B_{i_{n}}(\theta)\left(x^{i+1}\right)}{n^{i / 2}}$ where the $B_{i_{n}}(\theta)$ have the same properties with $A_{i_{n}}(\theta), h_{n}\left(f_{n}(\cdot, \theta), \theta\right)=$ $i d_{\mathbb{R}^{p}}(\cdot)+M_{n}(\cdot, \theta)$ where $M_{n}(x, \theta)$ is polynomial in $x$ of finite degree $\forall \theta \in \Theta$, and $\sup _{\theta \in \Theta}\left\|M_{n}(x, \theta)\right\|=o\left(n^{\frac{s-2}{2}}\right) \forall x \in \mathbb{R}^{p}$.

Proof: Let us call $M_{n}(x, \theta)=n^{\frac{s-1}{2}} M_{n}^{(s}(x, \theta)+R_{n}^{(s}(x, \theta)$ for $s \geq 3$. Proceed inductively. Let $s=3$, and therefore

$$
f_{n}(x, \theta)=A_{0}(\theta) x+\frac{1}{n^{1 / 2}} A_{1_{n}}(\theta)\left(x^{2}\right)=A_{0}(\theta) x+\frac{1}{n^{1 / 2}} A_{1_{n}}(\theta)\binom{x}{x} .
$$

Then

$$
h_{n}(x, \theta)=B_{0}(\theta) x+\frac{1}{n^{1 / 2}} B_{1_{n}}(\theta)\left(x^{2}\right)=B_{0}(\theta) x+\frac{1}{n^{1 / 2}} B_{1_{n}}(\theta)\binom{x}{x}
$$

and

$$
\begin{aligned}
h_{n}\left(f_{n}(x, \theta), \theta\right)= & B_{0}(\theta)\left(A_{0}(\theta) x+\frac{1}{n^{1 / 2}} A_{1_{n}}(\theta)\left(x^{2}\right)\right) \\
& +\frac{1}{n^{1 / 2}} B_{1_{n}}(\theta)\left(\left(A_{0}(\theta) x+\frac{1}{n^{1 / 2}} A_{1_{n}}(\theta)\left(x^{2}\right)\right)^{2}\right) \\
= & B_{0}(\theta) A_{0}(\theta) x+\frac{1}{n^{1 / 2}}\left[B_{0}(\theta) A_{1_{n}}(\theta)\left(x^{2}\right)+B_{1_{n}}(\theta)\binom{A_{0}(\theta) x}{A_{0}(\theta) x}\right] \\
& +\frac{1}{n}\left[B_{1_{n}}(\theta)\binom{A_{0}(\theta) x}{A_{1_{n}}(\theta)\left(x^{2}\right)}+B_{1_{n}}(\theta)\binom{A_{1_{n}}(\theta)\left(x^{2}\right)}{A_{0}(\theta) x}\right] \\
& +\frac{1}{n^{3 / 2}} B_{1_{n}}(\theta)\binom{A_{1_{n}}(\theta)\left(x^{2}\right)}{A_{1_{n}}(\theta)\left(x^{2}\right)} .
\end{aligned}
$$

Hence

$$
\begin{gathered}
B_{0}(\theta)=A_{0}^{-1}(\theta) \\
0=B_{0}(\theta) A_{1_{n}}(\theta)+B_{1_{n}}(\theta)\left(\begin{array}{cc}
A_{0}(\theta) & 0 \\
0 & A_{0}(\theta)
\end{array}\right)=> \\
B_{1_{n}}(\theta)\left(x^{2}\right)=-B_{0}(\theta) A_{1_{n}}(\theta)\left(\begin{array}{cc}
A_{0}(\theta) & 0 \\
0 & A_{0}(\theta)
\end{array}\right)^{-1}\left(x^{2}\right) \\
=
\end{gathered}
$$

and

$$
\begin{aligned}
M_{n}^{(3}(x, \theta) & =B_{1_{n}}(\theta)\binom{A_{0}(\theta) x}{A_{1_{n}}(\theta)\left(x^{2}\right)}+B_{1_{n}}(\theta)\binom{A_{1_{n}}(\theta)\left(x^{2}\right)}{A_{0}(\theta) x} \\
R_{n}^{3}(x, \theta) & =\frac{1}{n^{3 / 2}} B_{1_{n}}(\theta)\binom{A_{1_{n}}(\theta)\left(x^{2}\right)}{A_{1_{n}}(\theta)\left(x^{2}\right)}
\end{aligned}
$$

and it follows that

$$
h_{n}\left(f_{n}(x, \theta), \theta\right)=x+\frac{1}{n} M_{n}^{(3}(x, \theta)+R_{n}^{(3}(x, \theta) .
$$

As $A_{0}(\theta)$ is bounded away from zero uniformly w.r.t. $\theta, h_{n}$ is unique. Then due to the compactness of $\Theta$ the equicontinuity of $A_{1_{n}}(\theta)$ and the boundness away from zero of $A_{0}(\theta)$ uniformly w.r.t. $\theta$ the properties described in A.4.POL hold for $B_{1_{n}}(\theta)$ and consequently for $h_{n}$, as well. Furthermore, $M_{n}^{(33}(x, \theta)$, which due to the previous, is clearly a $3^{r d}$ - linear polynomial in $x$ $\forall \theta \in \Theta$, equicontinuous on $\Theta, \forall x^{i+1}$, and $\sup _{\theta \in \Theta}\left\|\frac{1}{n} M_{n}^{(3}(x, \theta)+R_{n}^{(3}(x, \theta)\right\|=$ $\sup _{\theta \in \Theta}\left\|M_{n}(x, \theta)\right\|=o\left(n^{-\frac{1}{2}}\right) \forall x \in \mathbb{R}^{p}$. For $s=4$ (see Arvanitis and Demos [2] for analytic proof) we proceed in the same spirit and we have that

$$
f_{n}(x, \theta)=A_{0}(\theta) x+\frac{1}{n^{1 / 2}} A_{1_{n}}(\theta)\left(x^{2}\right)+\frac{1}{n^{2 / 2}} A_{2_{n}}(\theta)\left(x^{3}\right) .
$$

Then

$$
h_{n}(x, \theta)=B_{0}(\theta) x+\frac{1}{n^{1 / 2}} B_{1_{n}}(\theta)\left(x^{2}\right)+\frac{1}{n} B_{2_{n}}(\theta)\left(x^{3}\right),
$$

where $B_{0}(\theta)$ and $B_{1_{n}}(\theta)$ as before, and

$$
B_{2_{n}}(\theta)\left(x^{3}\right)=-B_{0}(\theta) A_{2_{n}}(\theta)\left(A_{0}^{-1}(\theta) x, A_{0}^{-1}(\theta) x, A_{0}^{-1}(\theta) x\right)-M_{n}^{(3}\left(A_{0}^{-1}(\theta) x, \theta\right) .
$$

Obviously $h_{n}$ is unique, as well, due to the boundness away from zero of $A_{0}(\theta)$ uniformly w.r.t. $\theta$. Further, due to the compactness of $\Theta$ the equicontinuity of $A_{i_{n}}(\theta)$ and $M_{n}^{(3}\left(A_{0}^{-1}(\theta) x, \theta\right)$, and the boundness away from zero of $A_{0}(\theta)$ uniformly w.r.t. $\theta$ the properties described in A.4-POL hold for $h_{n}$, as well. Furthermore, $M_{n}^{(4}(x, \theta)$ is, again, clearly a $4^{t h}$ - linear polynomial in $x \forall \theta \in \Theta$, equicontinuous and $\sup _{\theta \in \Theta}\left\|\frac{1}{n^{3 / 2}} M_{n}^{(4}(x, \theta)+R_{n}^{(4}(x, \theta)\right\|=$ $\sup _{\theta \in \Theta}\left\|M_{n}(x, \theta)\right\|=o\left(n^{-1}\right) \forall x \in \mathbb{R}^{p}$.

Now, suppose that the result holds for $s=k$. For $s=k+1$ choose $B_{0}(\theta)=A_{0}^{-1}(\theta), B_{i_{n}}(\theta)=B_{i_{n}}^{*}(\theta)$ for $i=1, \ldots, k-2$, where $B_{i_{n}}^{*}(\theta)$ is the $i^{\text {th }}$ coefficient of the $h_{n}$ in the previous step and identify $B_{k-1_{n}}(\theta)$ by

$$
B_{k-1_{n}}(\theta)\left(x^{k}\right)=-A_{k-1_{n}}(\theta)\left(\left(A_{0}^{-1}(\theta) x\right)^{k}\right)-M_{n}^{(k}\left(A_{0}^{-1}(\theta) x, \theta\right) .
$$

Notice that due to the properties of $A_{0}(\theta)$ the solution exists, and it is unique, and that $B_{k-1_{n}}(\theta)$ is equicontinuous on $\Theta, \forall x^{i+1}$. Furthermore, $M_{n}^{(k+1}(x, \theta)$ is a composition of $B_{k-1_{n}}(\theta), B_{i_{n}}(\theta)$ and $A_{i_{n}}(\theta)$ for $i=1, \ldots, k-2$, and a $(k+1)^{s t}$ - linear polynomial in $x \forall \theta \in \Theta$. Hence

$$
h_{n}\left(f_{n}(x, \theta), \theta\right)=i d_{\mathbb{R}^{p}}(\cdot)+\frac{1}{n^{k / 2}} M_{n}^{(k+1}(x, \theta)+R_{n}^{(k+1}(x, \theta),
$$

where $R_{n}^{(k+1}(x, \theta)$ is a sum of compositions of $B_{i_{n}}(\theta)$ and $A_{i_{n}}(\theta)$ for $i=$ $0, \ldots, k-2$ and in $n$ with powers $-(k+1)$ up to $-(k+1) / 2$. Hence $R_{n}^{(k+1}(x, \theta)$ is a $(k+1)^{s t}$ - linear polynomial in $x \forall \theta \in \Theta$, as well, and
$\sup _{\theta \in \Theta}\left\|\frac{1}{n^{k / 2}} M_{n}^{(k+1}(x, \theta)+R_{n}^{(k+1}(x, \theta)\right\|=\sup _{\theta \in \Theta}\left\|M_{n}(x, \theta)\right\|=o\left(n^{-\frac{k-1}{2}}\right)$ $\forall x \in \mathbb{R}^{p}$.

Remark R. 3 In the notation of the proof of lemma AL. 2 the previous result implies that for $x \in \mathcal{H}_{n}^{c}(C)$

$$
h_{n}\left(f_{n}(x, \theta), \theta\right)=x+o\left(n^{\frac{s-2}{2}}\right)
$$

where the $o\left(n^{\frac{s-2}{2}}\right)$ is independent of $x$ and $\theta$.
We are now ready to prove the aforementioned theorem.
Proof of Theorem 3.1. Assume first without loss of generality that $p=q$, for if $p<q$, consider

$$
f_{n}^{*}(\theta, x)=\left(\begin{array}{cc}
A_{0}(\theta) & 0 \\
0 & I_{q-p}
\end{array}\right)+\sum_{i=1}^{s-1} \frac{1}{n^{i / 2}} A_{i_{n}}^{*}(\theta)\left(x^{i+1}\right)
$$

where $A_{i_{n}}^{*}(\theta)\left(x^{i+1}\right)=\binom{A_{i_{n}}(\theta)\left(x^{i+1}\right)}{0_{q-p}}$. If $f_{n}^{*}\left(S_{n}\right)$ admits a valid Edgeworth expansion with the prescribed property, then so does $f_{n}\left(S_{n}\right)$ by lemma AL.1. It suffices to prove that

$$
\sup _{\theta \in \Theta}\left|P\left(f_{n}\left(S_{n}(\theta)\right) \in A\right)-\Psi_{n, s}^{*}(\theta)(A)\right|=o\left(n^{-\frac{s-2}{2}}\right)
$$

for an arbitrary Borel set $A$, due to the fact that any Normal distribution attributes to the boundary of such a set zero measure, hence then 12 would follow from Theorem 2.11 (and the subsequent Remark) of Bhattacharya and Rao (4]. Now

$$
\begin{aligned}
P\left(f_{n}\left(S_{n}, \theta\right) \in A\right) & =P\left(S_{n} \in f_{n}^{-1}(A, \theta)\right) \\
& =\int_{f_{n}^{-1}(A, \theta)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z+o\left(n^{-\frac{s-2}{2}}\right)
\end{aligned}
$$

uniformly over $A \in B_{\mathbb{R}^{p}}$ and $\theta$. Then notice that

$$
\begin{aligned}
& \int_{f_{n}^{-1}(A, \theta)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z \\
= & \int_{f_{n}^{-1}(A, \theta) \cap \mathcal{H}_{n}^{c}(C)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z+o\left(n^{-\frac{s-2}{2}}\right)
\end{aligned}
$$

where the last term is independent of $\theta$ due to the fact that

$$
\begin{aligned}
& \left|\int_{f_{n}^{-1}(A, \theta) \cap \mathcal{H}_{n}(C)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z\right| \\
\leq & \int_{\mathcal{H}_{n}(C)}\left(1+\sum_{i=1}^{s-2} \frac{\left|\pi_{i}(z, \theta)\right|}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z=o\left(n^{-\frac{s-2}{2}}\right)
\end{aligned}
$$

as in the proof of lemma AL.2, Now notice that due to A.4.POL and the compactness of $\Theta$, if $z \in f_{n}^{-1}(A, \theta) \cap \mathcal{H}_{n}^{c}(C)$ then $f_{n}(z, \theta) \in A$ and $\left\|f_{n}(z)\right\|<$ $C^{*} \ln ^{1 / 2} n$ for some $C^{*}$ independent of $\theta$. Hence, substituting for $u=f_{n}(z, \theta)$ we have that due to remark R. $3 z=h_{n}(u, \theta)+o\left(n^{-\frac{s-2}{2}}\right)$ where the last term does not depend on $\theta$ or $z$, when $z \in \mathcal{H}_{n}^{c}\left(C^{*}\right)$. Hence

$$
\begin{aligned}
& \int_{f_{n}^{-1}(A, \theta) \cap \mathcal{H}_{n}^{c}(C)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z \\
= & \int_{A \cap \mathcal{H}_{n}^{c}\left(C^{*}\right)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}\left(h_{n}(u, \theta)+o\left(n^{-\frac{s-2}{2}}\right), \theta\right)}{n^{i / 2}}\right) \kappa(u, \theta) d u \\
= & \int_{A \cap \mathcal{H}_{n}^{c}\left(C^{*}\right)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}^{*}(u, \theta)}{n^{i / 2}}\right) \varphi_{K(\theta)}(u) d u+o\left(n^{-\frac{s-2}{2}}\right)
\end{aligned}
$$

where $K(\theta)=A_{0}(\theta) V(\theta) A_{0}(\theta), \kappa(u, \theta)=\frac{\varphi_{\Sigma(\theta)}\left(h_{n}(u, \theta)+o\left(n^{-\frac{s-2}{2}}\right)\right)}{\operatorname{det}\left(A_{0}(\theta)+O\left(n^{-\frac{1}{2}}\right)\right)}$ and the $\pi_{i}^{*} s$ are obtained by expanding and holding terms of the relevant order. Due to assumptions A.4, A.4 and the definition of $B_{i_{n}}(\theta)\left(x^{i+1}\right) s$, the $\pi_{i}^{*} s$ are equicontinuous in $\theta \forall u \in \mathbb{R}^{p}$ and the terms in $o\left(n^{-\frac{s-2}{2}}\right)$ are independent of $\theta$. Finally notice that since by an argument analogous to that of the proof
of lemma AL. 2

$$
\begin{aligned}
& \left|\int_{A \cap \mathcal{H}_{n}\left(C^{*}\right)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}^{*}(u, \theta)}{n^{i / 2}}\right) \varphi_{K(\theta)}(u) d u\right| \\
\leq & \left|\int_{\mathcal{H}_{n}\left(C^{*}\right)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}^{*}(u, \theta)}{n^{i / 2}}\right) \varphi_{K(\theta)}(u) d u\right|=o\left(n^{-\frac{s-2}{2}}\right)
\end{aligned}
$$

where the last term is independent of $\theta$, we obtain that

$$
P\left(f_{n}\left(S_{n}, \theta\right) \in A\right)=\int_{A}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}^{*}(u, \theta)}{n^{i / 2}}\right) \varphi_{K(\theta)}(u) d u+o\left(n^{-\frac{s-2}{2}}\right)
$$

uniformly over $\Theta$. For the second part of the theorem notice that

$$
\begin{aligned}
& \int_{\mathbb{R}^{p}} K\left(\left(f_{n}(z, \theta)\right)^{m}\right)\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z \\
= & \int_{\mathcal{H}_{n}^{c}(C)} K\left(\left(f_{n}(z, \theta)\right)^{m}\right)\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z \\
& +\int_{\mathcal{H}_{n}(C)} K\left(\left(f_{n}(z, \theta)\right)^{m}\right)\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z
\end{aligned}
$$

and again due to an analogous argument as in the proof of lemma AL.2, the fact that $K$ is multilinear and the form of $f_{n}$ in assumption A.4.POL, the last integral is $o\left(n^{-\frac{s-2}{2}}\right)$ which is independent of $\theta$. Now exactly as in the previous part for $u=f_{n}(z, \theta)$

$$
\begin{aligned}
& \int_{\mathcal{H}_{n}^{c}(C)} K\left(\left(f_{n}(z, \theta)\right)^{m}\right)\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z \\
= & \int_{\mathcal{H}_{n}^{c}\left(C^{*}\right)} K\left(u^{m}\right)\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}\left(h_{n}(u, \theta)+o\left(n^{-\frac{s-2}{2}}\right), \theta\right)}{n^{i / 2}}\right) \kappa(u, \theta) d u
\end{aligned}
$$

and the result follows exactly as the previous one, by simply noticing that (some of) the remainders will also depend on $K\left(u^{m}\right)$ which is nevertheless polynomial.

The final result of this section, is partially a consequence of the previous theorem, and can be of convenience for the establishment of valid locally uniform Edgeworth expansions for estimators that asymptotically satisfy sufficiently smooth first order conditions with sufficiently high probability.

Theorem 3.2 Suppose that:
-POLFOC $M_{n}(\theta)$ satisfies $0_{p \times 1}=\sum_{i=0}^{s-2} \frac{1}{n^{i / 2}} \sum_{j=0}^{i+1} C_{i j_{n}}(\theta)\left(M_{n}(\theta)^{j}, S_{n}(\theta)^{i+1-j}\right)+$ $R_{n}(\theta)$ with probability $1-o\left(n^{-\frac{s-2}{2}}\right)$ independent of $\theta$ where $C_{i j_{n}}: \Theta \times$ $\mathbb{R}^{q^{i+1}} \rightarrow \mathbb{R}^{p}$ is $(i+1)$-linear $\forall \theta \in \Theta, C_{00_{n}}(\theta), C_{01_{n}}(\theta)$ are independent of $n$ and have rank $p \forall \theta \in \Theta, C_{i j_{n}}$ are equicontinuous on $\Theta, \forall x^{i+1}$,
-LUE $S_{n}(\theta)$ admits a locally uniform Edgeworth expansion that satisfies assumption A.4-EEQ,
${ }_{-U A T} \sup _{\theta \in \Theta} P\left(\left\|M_{n}(\theta)\right\|>C \ln ^{1 / 2} n\right)=o\left(n^{-\frac{s-2}{2}}\right)$ for some $C>0$ independent of $\theta$,
$-\mathrm{USR} \sup _{\theta \in \Theta} P\left(\left\|R_{n}(\theta)\right\|>\gamma_{n}\right)=o\left(n^{-\frac{s-2}{2}}\right)$ for some real sequence $\gamma_{n}=$ $o\left(n^{-\frac{s-2}{2}}\right)$ independent of $\theta$.
Then $M_{n}(\theta)$ admits a locally uniform Edgeworth expansion that satisfies assumption A.4-EEQ.

In order to prove this we need the following result.
Lemma 3.3 Suppose that $S_{n}(\theta)$ admits a locally uniform Edgeworth expansion that satisfies A.4-EEQ and that $U_{n}(\theta)$ is such that

$$
\sup _{\theta \in \Theta} P\left(U_{n}(\theta)=S_{n}(\theta)+R_{n}(\theta)\right)=1-o\left(n^{-\frac{s-2}{2}}\right)
$$

where $R_{n}$ satisfies condition 3.2-USR. Then $U_{n}(\theta)$ admits the same locally uniform Edgeworth expansion.

Proof of Lemma 3.3. Let $a=\frac{s-2}{2}$. Notice first that

$$
\begin{aligned}
& P\left(U_{n}(\theta) \in A\right) \\
\leq & P\left(U_{n}(\theta) \in A, U_{n}(\theta)=S_{n}(\theta)+R_{n}(\theta)\right)+P\left(U_{n}(\theta) \neq S_{n}(\theta)+R_{n}(\theta)\right) \\
\leq & P\left(S_{n}(\theta)+R_{n}(\theta) \in A,\left\|R_{n}(\theta)\right\| \leq \gamma_{n}\right)+P\left(\left\|R_{n}(\theta)\right\|>\gamma_{n}\right)+o\left(n^{-a}\right) \\
= & P\left(S_{n}(\theta) \in A-\gamma_{n}\right)+o\left(n^{-\frac{s-2}{2}}\right)
\end{aligned}
$$

where all the remainders in the previous display are independent of $\theta$. Now, as $S_{n}(\theta)$ admits a locally uniform Edgeworth expansion, we have that for an arbitrary Borel set $A$

$$
\begin{aligned}
P\left(S_{n}(\theta) \in A-\gamma_{n}\right) & =\int_{A-\gamma_{n} i_{q}}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z+o\left(n^{-a}\right) \\
& =\int_{\left(A-\gamma_{n} i_{q}\right) \cap \mathcal{H}_{n}^{c}(C)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z+o\left(n^{-a}\right)
\end{aligned}
$$

where $i_{q}$ is a $q \times 1$ vector of 1 's, $A-\gamma_{n} i_{q}$ denotes translation by $-\gamma_{n} i_{q}$, and the last term is independent of $\theta$ and $A$ (see also the beginning of the proof of theorem 3.1) and $\mathcal{H}_{n}^{c}(C)$ was defined in the proof of lemma AL.2. Now by a change of variables we have that for large enough $n$

$$
\begin{aligned}
& \int_{A \cap\left(\mathcal{H}_{n}^{c}(C)+\gamma_{n} i_{q}\right)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z \\
= & \int_{A \cap\left(\mathcal{H}_{n}^{c}(C)+\gamma_{n} i_{q}\right)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}\left(z-\gamma_{n} i_{q}, \theta\right)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}\left(z-\gamma_{n} i_{q}\right) d z .
\end{aligned}
$$

Expanding terms using the mean value theorem, holding terms of the relevant order due to the fact that A.4-EEQ we obtain that

$$
\begin{aligned}
\varphi_{\Sigma(\theta)}\left(z-\gamma_{n} i_{q}\right) & =\varphi_{\Sigma(\theta)}(z)+\gamma_{n} \varphi_{\Sigma(\theta)}\left(z-\gamma_{n}^{*} i_{q}\right)\left(\gamma_{n}^{*} i_{q}^{\prime} \Sigma^{-1}(\theta) i_{q}-i_{q}^{\prime} \Sigma^{-1}(\theta) z\right) \\
\pi_{i}\left(z-\gamma_{n} i_{q}, \theta\right) & =\pi_{i}(z, \theta)-\gamma_{n} i_{q}^{\prime} \frac{\partial \pi_{i}\left(z-\gamma_{n}^{* *} i_{q}, \theta\right)}{\partial z}
\end{aligned}
$$

where $\gamma_{n}^{*}, \gamma_{n}^{* *}$ lie between $0_{q \times 1}, \frac{\partial \pi_{i}(z, \theta)}{\partial z}$ is also polynomial in $z$, and there exists some $C^{*}>C$ such that

$$
\begin{aligned}
& \int_{A \cap\left(\mathcal{H}_{n}^{c}(C)+\gamma_{n}\right)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}\left(z-\gamma_{n} i_{q}, \theta\right)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}\left(z-\gamma_{n} i_{q}\right) d z \\
= & \int_{A \cap\left(\mathcal{H}_{n}^{c}(C)+\gamma_{n}\right)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z+R_{n}^{*}(\theta)
\end{aligned}
$$

where

$$
\begin{aligned}
& R_{n}^{*}(\theta) \\
& \leq \sum_{i=1}^{s-2} \int_{A \cap\left(\mathcal{H}_{n}^{c}(C)+\gamma_{n}\right)} \frac{\left|\gamma_{n}\right|}{n^{i / 2}} \sqrt{q}\left|\frac{\partial \pi_{i}\left(z-\gamma_{n}^{* *} i_{q}, \theta\right)}{\partial z}\right| \varphi_{\Sigma(\theta)}(z) d z \\
&+\sum_{i=1}^{s-2} \int_{A \cap\left(\mathcal{H}_{n}^{c}(C)+\gamma_{n}\right)} \frac{\left|\gamma_{n}\right|}{n^{i / 2}}\left|\pi_{i}(z, \theta)\right|\left\|\gamma_{n}^{*} i_{q}^{\prime} \Sigma^{-1}(\theta) i_{q}-i_{q}^{\prime} \Sigma^{-1}(\theta) z\right\| \\
& \times \varphi_{\Sigma(\theta)}\left(z-\gamma_{n}^{*} i_{q}\right) d z \\
&+\sum_{i=1}^{s-2} \int_{A \cap\left(\mathcal{H}_{n}^{c}(C)+\gamma_{n}\right)} \frac{\left|\gamma_{n}\right|^{2}}{n^{i / 2}} \sqrt{q}\left\|\frac{\partial \pi_{i}\left(z-\gamma_{n}^{* *} i_{q}, \theta\right)}{\partial z}\right\| \\
& \quad \times\left\|\gamma_{n}^{*} i_{q}^{\prime} \Sigma^{-1}(\theta) i_{q}-i_{q}^{\prime} \Sigma^{-1}(\theta) z\right\| \varphi_{\Sigma(\theta)}\left(z-\gamma_{n}^{*} i_{q}\right) d z \\
&+\int_{A \cap\left(\mathcal{H}_{n}^{( }(C)+\gamma_{n}\right)}\left|\gamma_{n}\right| \sqrt{q}\left\|\gamma_{n}^{*} i_{q}^{\prime} \Sigma^{-1}(\theta) i_{q}-i_{q}^{\prime} \Sigma^{-1}(\theta) z\right\| \\
& \times \varphi_{\Sigma(\theta)}\left(z-\gamma_{n}^{*} i_{q}\right) d z
\end{aligned}
$$

which is less than or equal to

$$
\begin{aligned}
& \sum_{i=1}^{s-2} \int_{\Sigma^{*} A \cap\left(\mathcal{H}_{n}^{c}\left(\left\|\Sigma^{*}\right\| C\right)+\Sigma^{*} \gamma_{n}\right)} \frac{\left|\gamma_{n}\right|}{n^{i} / 2} \sqrt{q} \\
& \times\left|\frac{\partial \pi_{i}\left(\Sigma(\theta) z-\Sigma(\theta) \gamma_{n}^{* *} i_{q}, \theta\right)}{\partial z}\right| \varphi(z) d z \\
& +\sum_{i=1}^{s-2} \int_{\Sigma^{*} A \cap\left(\mathcal{H}_{n}^{c}\left(\left\|\Sigma^{*}\right\| C\right)+\Sigma^{*} \gamma_{n}\right)} \frac{\left|\gamma_{n}\right|}{n^{i / 2}}\left|\pi_{i}(\Sigma(\theta) z, \theta)\right| \\
& \times\left\|\gamma_{n}^{*} i_{q}^{\prime} \Sigma^{-1}(\theta) i_{q}-i_{q}^{\prime} \Sigma^{-1}(\theta) z\right\| \varphi\left(z-\Sigma^{-1 / 2}(\theta) \gamma_{n}^{*} i_{q}\right) d z \\
& +\sum_{i=1}^{s-2} \int_{\Sigma^{*} A \cap\left(\mathcal{H}_{n}^{c}\left(\left\|\Sigma^{*}\right\| C\right)+\Sigma^{*} \gamma_{n}\right)} \frac{\left|\gamma_{n}\right|^{2}}{n^{i / 2}} \sqrt{q}\left\|\frac{\partial \pi_{i}\left(\Sigma(\theta) z-\Sigma(\theta) \gamma_{n}^{* *} i_{q}, \theta\right)}{\partial z}\right\| \\
& \times\left\|\gamma_{n}^{*} i_{q}^{\prime} \Sigma^{-1}(\theta) i_{q}-i_{q}^{\prime} \Sigma^{-1 / 2}(\theta) z\right\| \varphi\left(z-\Sigma^{-1 / 2}(\theta) \gamma_{n}^{*} i_{q}\right) d z \\
& +\int_{\Sigma^{*} A \cap\left(\mathcal{H}_{n}^{c}\left(\left\|\Sigma^{*}\right\| C\right)+\Sigma^{*} \gamma_{n}\right)}\left|\gamma_{n}\right| \sqrt{q}\left\|\gamma_{n}^{*} i_{q}^{\prime} \Sigma^{-1}(\theta) i_{q}-i_{q}^{\prime} \Sigma^{-1}(\theta) z\right\| \\
& \times \varphi\left(z-\Sigma^{-1 / 2}(\theta) \gamma_{n}^{*} i_{q}\right) d z
\end{aligned}
$$

$\Sigma^{*}$ the diagonal matrix with elements consisting of the inverse of $\lambda_{*}=$ $\inf _{\theta \in \Theta} \sqrt{\lambda_{\min } \Sigma(\theta)}$ and notice that on $\mathcal{H}_{n}^{c}\left(\left\|\Sigma^{*}\right\| C\right)+\Sigma^{*} \gamma_{n}$

$$
\begin{aligned}
& \varphi\left(z-\Sigma^{-1 / 2}(\theta) \gamma_{n}^{*} i_{q}\right) \\
= & \varphi(z) \exp \left(z^{\prime} \Sigma^{-1 / 2}(\theta) \gamma_{n}^{*} i_{q}\right) \exp \left(\left(\gamma_{n}^{*}\right)^{2} i_{q}^{\prime} \Sigma^{-1}(\theta) i_{q}\right) \\
\leq & \varphi(z) \exp \left(\frac{q}{\lambda_{*}}\left(C\left(\ln ^{1 / 2} n\right) \gamma_{n}^{*}+\left(\gamma_{n}^{*}\right)^{2}\right)\right)
\end{aligned}
$$

furthermore due to the properties of $\Sigma(\theta)$ and the fact that the $\pi_{i}$ and their derivatives are polynomials there exist positive constants independent of $z$ and $\theta$ such that $\left|\pi_{i}(\Sigma(\theta) z, \theta)\right| \leq \sum_{j=1}^{q_{i}} c_{i j}\|z\|^{j},\left\|\frac{\partial \pi_{i}\left(\Sigma(\theta) z-\Sigma(\theta) \gamma_{n}^{* *} i_{q}, \theta\right)}{\partial z}\right\| \leq$
$\sum_{j=1}^{q_{i}^{*}} c_{i j}^{*}\left(\|z\|^{j}+\left|\gamma_{n}^{*}\right|^{j}\right)$, hence we obtain that

$$
\begin{aligned}
& \left|R_{n}^{*}(\theta)\right| \\
\leq & \sum_{i=1}^{s-2} \sum_{j=1}^{q_{i}^{*}} \int_{\mathcal{H}_{n}^{c}\left(C^{*}\right)} \frac{\left|\gamma_{n}\right|}{n^{i / 2}} \sqrt{q}\left(c_{i j}^{*}\left(\|z\|^{j}+\left|\gamma_{n}^{*}\right|^{j}\right)\right) \varphi(z) d z \\
& +\sum_{i=1}^{s-2} \sum_{j=1}^{q_{i}} \int_{\mathcal{H}_{n}^{c}\left(C^{*}\right)} \frac{\left|\gamma_{n}\right|}{n^{i / 2}} c_{i j}\|z\|^{j} \frac{q}{\lambda_{*}^{2}}\left(\left|\gamma_{n}^{*}\right|+\|z\|\right) \\
& \times \exp \left(\frac{q}{\lambda_{*}}\left(C\left(\ln ^{1 / 2} n\right) \gamma_{n}^{*}+\left(\gamma_{n}^{*}\right)^{2}\right)\right) \varphi(z) d z \\
& +\sum_{i=1}^{s-2} \sum_{j=1}^{q_{i}^{*}} \int_{\mathcal{H}_{n}^{c}\left(C^{*}\right)} \frac{\left|\gamma_{n}\right|^{2}}{n^{i / 2}} \sqrt{q}\left(c_{i j}^{*}\left(\|z\|^{j}+\left|\gamma_{n}^{*}\right|^{j}\right)\right) \\
& \times \frac{q}{\lambda_{*}^{2}}\left(\left|\gamma_{n}^{*}\right|+\|z\|\right) \exp \left(\frac{q}{\lambda_{*}}\left(C\left(\ln ^{1 / 2} n\right) \gamma_{n}^{*}+\left(\gamma_{n}^{*}\right)^{2}\right)\right) \varphi(z) d z \\
& +\int_{\mathcal{H}_{n}^{c}\left(C^{*}\right)}\left|\gamma_{n}\right| \sqrt{q} \frac{q}{\lambda_{*}^{2}}\left(\left|\gamma_{n}^{*}\right|+\|z\|\right) \exp \left(\frac{q}{\lambda_{*}}\left(C\left(\ln ^{1 / 2} n\right) \gamma_{n}^{*}+\left(\gamma_{n}^{*}\right)^{2}\right)\right) \varphi(z) d z
\end{aligned}
$$

for some large enough $C^{*}$ and each of these terms is $o\left(n^{-\frac{s-2}{2}}\right)$ and independent of $\theta$ due to the properties of $\gamma_{n}$ and equation (A.8) in the proof of Lemma 2 in Magdalinos [11] that implies

$$
\int_{\mathcal{H}_{n}^{c}\left(C^{*}\right)}\|z\|^{j} \varphi(z) d z=K_{j}\left(1-o\left(n^{-\frac{s-2}{2}}\right)\right)
$$

for $C^{*}$ large enough and any $j$. Finally

$$
\begin{aligned}
& \int_{A \cap\left(\mathcal{H}_{n}^{c}(C)+\gamma_{n}\right)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z \\
= & \int_{A}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z+o\left(n^{-\frac{s-2}{2}}\right)
\end{aligned}
$$

where the last term is independent of $\theta$ due to the fact that

$$
\begin{aligned}
& \int_{A \cap\left(\mathcal{H}_{n}^{c}(C)+\gamma_{n}\right)^{c}}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z \\
\leq & \int_{\mathcal{H}_{n}(C)}\left(1+\sum_{i=1}^{s-2} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{\Sigma(\theta)}(z) d z=o\left(n^{-\frac{s-2}{2}}\right)
\end{aligned}
$$

and the last term is independent of $\theta$, due to the properties of $\gamma_{n}$ and equation (A.8) in the proof of Lemma 2 in Magdalinos [11].

Proof of Theorem 3.2: For analytic proof please see Arvanitis and Demos [2]. We first show that

$$
M_{n}(\theta)=\sum_{i=0}^{s-2} \frac{1}{n^{i / 2}} A_{i_{n}}(\theta)\left(S_{n}(\theta)^{i+1}\right)+Q_{n}(\theta)
$$

with probability $1-o\left(n^{-\frac{s-2}{2}}\right)$ independent of $\theta$ with unique $A_{i_{n}}(\theta)$ satisfying assumption A.4POL and $Q_{n}(\theta)$ satisfying condition 3.2-USR. We proceed inductively. When $s=3$, we have that with probability $1-o\left(n^{-\frac{s-2}{2}}\right)$ independent of $\theta, \sup _{\theta \in \Theta} P\left(\left\|R_{n}(\theta)\right\|>\gamma_{n}\right)=o\left(n^{-\frac{1}{2}}\right)$, we have

$$
\begin{gathered}
0_{p \times 1}=C_{00_{n}}(\theta)\left(S_{n}(\theta)\right)+C_{01_{n}}(\theta)\left(M_{n}(\theta)\right)+\frac{1}{n^{1 / 2}} C_{10_{n}}(\theta)\left(S_{n}(\theta)^{2}\right) \\
+\frac{1}{n^{1 / 2}} C_{11_{n}}(\theta)\left(M_{n}(\theta), S_{n}(\theta)\right)+\frac{1}{n^{1 / 2}} C_{12_{n}}(\theta)\left(M_{n}(\theta)^{2}\right)+R_{n}(\theta)=> \\
M_{n}(\theta)=-C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta)\left(S_{n}(\theta)\right)-\frac{1}{n^{1 / 2}} C_{01_{n}}^{-1}(\theta) C_{10_{n}}(\theta)\left(S_{n}(\theta)^{2}\right) \\
-\frac{1}{n^{1 / 2}} C_{00_{n}}^{-1}(\theta) C_{11_{n}}(\theta)\left(M_{n}(\theta), S_{n}(\theta)\right)-\frac{1}{n^{1 / 2}} C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\left(M_{n}(\theta)^{2}\right)
\end{gathered}
$$

$-C_{01_{n}}^{-1}(\theta) R_{n}(\theta)$. Substituting out, from the right hand side, $M_{n}(\theta)$ by $-C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta)\left(S_{n}(\theta)\right)$ and collecting terms we get:

$$
M_{n}(\theta)=A_{0_{n}}(\theta)\left(S_{n}(\theta)\right)+\frac{1}{n^{1 / 2}} A_{1_{n}}(\theta)\left(S_{n}(\theta)^{2}\right)+\frac{1}{n} Q_{n}^{(3}(\theta)+R_{n}^{(3}(\theta)
$$

where $A_{0_{n}}(\theta)=-C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta)$,
$A_{1_{n}}(\theta)=C_{01_{n}}^{-1}(\theta) C_{11_{n}}(\theta)\left(\begin{array}{cc}C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta) & 0 \\ 0 & I d_{q}\end{array}\right)-C_{01_{n}}^{-1}(\theta) C_{10_{n}}(\theta)$
$-C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\left(\begin{array}{cc}C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta) & 0 \\ 0 & C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta)\end{array}\right)$,
$Q_{n}^{(3}(\theta)=C_{01_{n}}^{-1}(\theta) C_{11_{n}}(\theta)\binom{C_{01_{n}}^{-1}(\theta) C_{10_{n}}(\theta)\left(S_{n}(\theta)^{2}\right)}{,S_{n}(\theta)}$
$+C_{01_{n}}^{-1}(\theta) C_{11_{n}}(\theta)\binom{C_{01_{n}}^{-1}(\theta) C_{11_{n}}(\theta)\left(M_{n}(\theta), S_{n}(\theta)\right)+C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\left(M_{n}(\theta)^{2}\right)}{,S_{n}(\theta)}$
$-C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\binom{C_{0 n_{n}}^{-1}(\theta) C_{00_{n}}(\theta)\left(S_{n}(\theta)\right), C_{01_{n}}^{-1}(\theta) C_{10_{n}}(\theta)\left(S_{n}(\theta)^{2}\right)}{+C_{01_{n}}^{-1}(\theta) C_{11_{n}}(\theta)\left(M_{n}(\theta), S_{n}(\theta)\right)+C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\left(M_{n}(\theta)^{2}\right)}$
$-C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\binom{C_{01_{n}}^{-1}(\theta) C_{10_{n}}(\theta)\left(S_{n}(\theta)^{2}\right)}{,C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta)\left(S_{n}(\theta)\right)}$
$-C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\binom{C_{01_{n}}^{-1}(\theta) C_{11_{n}}(\theta)\left(M_{n}(\theta), S_{n}(\theta)\right)+C_{00_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\left(M_{n}(\theta)^{2}\right)}{,C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta)\left(S_{n}(\theta)\right)}$,
and $R_{n}^{(3}(\theta)=-\frac{1}{n^{3 / 2}} C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\binom{C_{01_{n}}^{-1}(\theta) C_{10_{n}}(\theta)\left(S_{n}(\theta)^{2}\right)}{,C_{01_{n}}^{-1}(\theta) C_{10_{n}}(\theta)\left(S_{n}(\theta)^{2}\right)}$

$$
\begin{aligned}
& -\frac{1}{n^{3 / 2}} C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\binom{C_{01_{n}}^{-1}(\theta) C_{10_{n}}(\theta)\left(S_{n}(\theta)^{2}\right),}{C_{01_{n}}^{-1}(\theta) C_{11_{n}}(\theta)\left(M_{n}(\theta), S_{n}(\theta)\right)+C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\left(M_{n}(\theta)^{2}\right)} \\
& -\frac{1}{n^{3 / 2}} C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\binom{C_{01_{n}}^{-1}(\theta) C_{11_{n}}(\theta)\left(M_{n}(\theta), S_{n}(\theta)\right)+C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\left(M_{n}(\theta)^{2}\right),}{C_{01_{n}}^{-1}(\theta) C_{10_{n}}(\theta)\left(S_{n}(\theta)^{2}\right)} \\
& -\frac{1}{n^{3 / 2}} C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\binom{C_{01_{n}}^{-1}(\theta) C_{11_{n}}(\theta)\left(M_{n}(\theta), S_{n}(\theta)\right)+C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\left(M_{n}(\theta)^{2}\right),}{C_{01_{n}}^{-1}(\theta) C_{11_{n}}(\theta)\left(M_{n}(\theta), S_{n}(\theta)\right)+C_{01_{n}}^{-1}(\theta) C_{12_{n}}(\theta)\left(M_{n}(\theta)^{2}\right)} \\
& -C_{0}^{-1}(\theta) R_{n}(\theta) .
\end{aligned}
$$

It is obvious that $A_{0_{n}}(\theta)$ and $A_{1_{n}}(\theta)$ are defined uniquely and have the required properties due to analogous properties of $C_{i j_{n}}(\theta)$. Furthermore due to the conditions structuring the theorem, lemma AL. 2 and the compactness of $\Theta$ it is easy to see that there exists a sequence $\gamma_{n}^{\prime}=o\left(n^{-\frac{1}{2}}\right)$ such that condition 3.2 USR holds for $\frac{1}{n} Q_{n}^{(3)}(\theta)+R_{n}^{(3)}(\theta)$.

Suppose now that $M_{n}(\theta)$ has the following expansion for $s=k$

$$
M_{n}(\theta)=\sum_{i=0}^{k-2} \frac{1}{n^{i / 2}} A_{i_{n}}(\theta)\left(S_{n}(\theta)^{i+1}\right)+\frac{1}{n^{(k-1) / 2}} Q_{n}^{(k}(\theta)+R_{n}^{(k}(\theta) .
$$

Then for $s=k+1$ we obtain $A_{(k-1)_{n}}(\theta)=Q_{n}^{(k}(\theta)+\sum_{j=0}^{k}(-1)^{j+1} C_{01_{n}}^{-1}(\theta) C_{(k-1) j_{n}}(\theta) K_{j}$
where $K_{0}=\left(\begin{array}{cccc}I d_{q} & 0 & 0 & 0 \\ 0 & I d_{q} & 0 & \vdots \\ 0 & 0 & \ddots & 0 \\ 0 & \cdots & 0 & I d_{q}\end{array}\right), K_{1}=\left(\begin{array}{cccc}C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta) & 0 & 0 & 0 \\ 0 & I d_{q} & 0 & \vdots \\ 0 & 0 & \ddots & 0 \\ 0 & \cdots & 0 & I d_{q}\end{array}\right)$,
$\ldots$, and $K_{k}=\left(\begin{array}{cccc}C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta) & 0 & 0 & 0 \\ 0 & C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta) & 0 & \vdots \\ 0 & 0 & \ddots & 0 \\ 0 & \cdots & 0 & C_{01_{n}}^{-1}(\theta) C_{00_{n}}(\theta)\end{array}\right)$,
and, as $C_{01_{n}}(\theta)$ is full rank, it is unique. Again $A_{(k-1)_{n}}$ has the required properties due to analogous properties of $C_{i j_{n}}(\theta)$. Furthermore $Q_{n}$ is determined by the $o\left(\frac{1}{n^{(k-1) / 2}}\right)$ terms of

$$
\begin{aligned}
& -C_{01_{n}}^{-1}(\theta) \sum_{i=1}^{k-1} \frac{1}{n^{i / 2}} \sum_{j=0}^{i+1} C_{i j_{n}}(\theta)\left(\left(\sum_{l=0}^{k-2} \frac{1}{n^{l / 2}} A_{l_{n}}(\theta)\left(S_{n}(\theta)^{l+1}\right)\right)^{j}, S_{n}(\theta)^{i+1-j}\right) \\
& -C_{01_{n}}^{-1}(\theta) R_{n}(\theta)
\end{aligned}
$$

(the largest order of which is $O\left(\frac{1}{n^{k / 2}}\right)$ ) and again due to the conditions structuring the theorem, lemma AL. 2 and the compactness of $\Theta$ it is easy to see that there exists a sequence $\gamma_{n}^{\prime}=o\left(n^{-\frac{k-1}{2}}\right)$ such that condition 3.2 USR holds for $Q_{n}(\theta)$. In the light of lemma 3.3 the result would follow
if $\sum_{i=0}^{s-2} \frac{1}{n^{i / 2}} A_{i_{n}}(\theta)\left(S_{n}(\theta)^{i+1}\right)$ admits an analogous Edgeworth expansion. This in turn follows by theorem 3.1, which applies due to the properties of the $A_{i_{n}}(\theta)$ established previously and due to condition 3.2 LUE.

We will make repeated use of this result in the following section.

## 4 Example

In this section we present a simple example that utilizes the previous results in order to establish the validity of several M-type (mainly GMM and indirect) estimators in the context of a $\operatorname{GARCH}(1,1)$ model.

Assumption A. 5 Consider the set of ergodic and covariance stationary processes defined by the recursion

$$
\begin{aligned}
& y_{j}^{2}=\varepsilon_{j}^{2} h_{j} \\
& h_{j}=\theta_{1}\left(1-\theta_{2}-\theta_{3}\right)+\left(\theta_{2} z_{j-1}^{2}+\theta_{3}\right) h_{j-1}
\end{aligned}
$$

where the $\left(\varepsilon_{j}\right)$ are iid, with $E \varepsilon_{0}=0, E \varepsilon_{0}^{2}=1, E\left|\varepsilon_{0}\right|^{4 s+4}<+\infty$ the distribution of $\varepsilon_{0}$ admits a positive continuous density and $\theta=\left(\theta_{1}, \theta_{2}, \theta_{3}\right)^{\prime} \in$ $\Theta=\left[\underline{\eta}_{\omega}, \bar{\eta}_{\omega}\right] \times\left[\underline{\eta}_{\alpha}, \bar{\eta}_{\alpha}\right] \times\left[\underline{\eta}_{\beta}, \bar{\eta}_{\beta}\right]$ where $\underline{\eta}_{\omega}, \underline{\eta}_{\alpha}, \underline{\eta}_{\beta}>0$ and for any $\theta \in \Theta$, $E\left(\theta_{2}\left|\varepsilon_{0}\right|^{2}+\theta_{3}\right)^{2 s+2}<1$.

This assumption implies that $E\left(h_{j}^{s+1}(\theta)\right)$ exists and is independent of $j$ and thereby due to Theorem 3.1 of Bougerol [5] that the recursion defines almost surely unique stationary and ergodic processes represented by

$$
y_{j}^{2}=\varepsilon_{j}^{2} \theta_{1}\left(1-\theta_{2}-\theta_{3}\right)\left(1+\sum_{r=0}^{\infty} \prod_{p=0}^{r}\left(\theta_{2} \varepsilon_{j-p-1}^{2}+\theta_{3}\right)\right)
$$

For any $\theta \in \times$ let $X_{j}(\theta)=\left(\begin{array}{llll}y_{j}^{2} & y_{j}^{4} & y_{j}^{2} y_{j-1}^{2} & y_{j}^{2} y_{j-2}^{2}\end{array}\right)^{\prime}$.
Proposition 1 Under assumption A.5 $S_{n}(\theta)=\frac{1}{\sqrt{n}} \sum_{i=1}^{n}\left(X_{i}(\theta)-E X_{1}(\theta)\right)$ admits a locally uniform Edgeworth expansion of order $s-2$ over $\Theta$, with $\Psi_{n, s}(\theta)$ the formal Edgeworth distribution. Moreover the polynomials of the density of $\Psi_{n, s}(\theta)$ satisfy assumption A.4-EEQ.

Proof: The logic of this proof is to establish condition A. 2 and apply theorem 2.1. For the establishment of assumption A.2-SM we employ lemma 2.6. First notice that a dominated convergence argument along with the condition $E\left(\theta_{2}\left|\varepsilon_{0}\right|^{2}+\theta_{3}\right)^{2 s+2}<1$ and the monotonicity of $h$ w.r.t. $\theta$
in A.5, imply that $E\left(y_{j}^{m}(\theta)\right)$ exists and is continuous on $\Theta$ for any $m=$ $1, \ldots, 4 s+4$. Therefore $\sup _{\theta \in \times} E\left\|X_{0}(\theta)\right\|^{s+1}<+\infty$ establishing A.2-M. This also implies that if the formal Edgeworth expansion is valid, the polynomials of its density, which are equicontinuous functions of these moments and the covariance matrix would satisfy assumption A.4.EEQ. Let us now call $A_{j}=\left(\theta_{2} \varepsilon_{j}^{2}+\theta_{3}\right), \Omega_{m}=\left(1+\sum_{r=0}^{m-1} \prod_{p=0}^{r} A_{j-p-1}\right), \omega=\theta_{1}\left(1-\theta_{2}-\theta_{3}\right)$, and $\Omega_{m, k^{*},, j}=\left(1+\sum_{r=0}^{m-k^{*}-1} \prod_{p=0}^{r} A_{j-k^{*}-p-1}\right)$. Hence,

$$
\begin{aligned}
E\left|y_{j}^{2}-\omega \varepsilon_{j}^{2} \Omega_{m}\right| & =\theta_{1}\left(\theta_{2}+\theta_{3}\right)^{m+1} \\
& \leq \bar{\eta}_{\omega}\left(\bar{\eta}_{\alpha}+\bar{\eta}_{\beta}\right)^{m+1} .
\end{aligned}
$$

Analogously, for any $0 \leq k^{*}<m$ notice that $h_{j} h_{j-k^{*}}-\omega^{2} \Omega_{m} \Omega_{m-k^{*}}$
$=\omega h_{j} \sum_{r=m-k^{*}}^{\infty} \prod_{p=0}^{r}\left(\theta_{2} \varepsilon_{j-k^{*}-p-1}^{2}+\theta_{3}\right)+h_{j-k^{*}} \omega \sum_{r=m}^{\infty} \prod_{p=0}^{r}\left(\theta_{2} \varepsilon_{j-p-1}^{2}+\theta_{3}\right)$
$-\omega^{2} \sum_{r=m}^{\infty} \prod_{p=0}^{r}\left(\theta_{2} \varepsilon_{j-p-1}^{2}+\theta_{3}\right) \sum_{r=m-k^{*}}^{\infty} \prod_{p=0}^{r}\left(\theta_{2} \varepsilon_{j-k^{*}-p-1}^{2}+\theta_{3}\right)$
$=\omega h_{j} \sum_{r=m-k^{*}}^{\infty} \prod_{p=0}^{r}\left(\theta_{2} \varepsilon_{j-k^{*}-p-1}^{2}+\theta_{3}\right)+\omega^{2} \Omega_{m, k^{*}, j} \sum_{r=m}^{\infty} \prod_{p=0}^{r}\left(\theta_{2} \varepsilon_{j-p-1}^{2}+\theta_{3}\right)$
and therefore due to the inequality of Cauchy-Schwarch, applicable due to the
moment existence conditions described before, we have that $E\left|y_{j}^{2} y_{j-k^{*}}^{2}-\omega^{2} \varepsilon_{j}^{2} \varepsilon_{j-k^{*}}^{2} \Omega_{m} \Omega_{m-k^{*}}\right|=$
$\omega E\left(h_{j} \varepsilon_{j-k^{*}}^{2} \sum_{r=m-k^{*}}^{\infty} \prod_{p=0}^{r} A_{j-k^{*}-p-1}\right)$
$+\omega^{2} E\left(\varepsilon_{j-k^{*}}^{2} \Omega_{m, k^{*}, j} \sum_{r=m}^{\infty} \prod_{p=0}^{r} A_{j-p-1}\right)$
$\leq \omega E^{1 / 4}\left(h_{j}^{4}\right) E^{1 / 4}\left(\varepsilon_{j-k^{*}}^{8}\right) E^{1 / 2}\left(\sum_{r=m-k^{*}}^{\infty} \prod_{p=0}^{r} A_{j-k^{*}-p-1}\right)^{2}$
$+\omega^{2} E^{1 / 2}\left(\varepsilon_{j-k^{*}}^{4}\right) E^{1 / 2}\left(\sum_{r=m}^{\infty} \prod_{p=0}^{r} A_{j-p-1}\right)^{2}$
$+\omega^{2} E^{1 / 4}\left(\varepsilon_{j-k^{*}}^{8}\right) E^{1 / 4}\left(\sum_{r=0}^{m-k^{*}-1} \prod_{p=0}^{r} A_{j-k^{*}-p-1}\right)^{4} E^{1 / 2}\left(\sum_{r=m}^{\infty} \prod_{p=0}^{r} A_{j-p-1}\right)^{2}$
$=\omega E^{1 / 4}\left(h_{0}^{4}\right) E^{1 / 4}\left(\varepsilon_{0}^{8}\right)\binom{\sum_{r=m-k^{*}}^{\infty} E\left(\prod_{p=0}^{r} A_{j-k^{*}-p-1}^{2}\right)}{+2 \sum_{r^{*}>r=m-k^{*}}^{\infty} E\left(\prod_{p=0}^{r} A_{j-k^{*}-p-1} \prod_{p=0}^{r^{*}} A_{j-k^{*}-p-1}\right)}^{1 / 2}$
$+\omega^{2} E^{1 / 2}\left(\varepsilon_{0}^{4}\right)\left(\sum_{r=m}^{\infty} E\left(\prod_{p=0}^{r} A_{j-p-1}^{2}\right)+2 E\left(\sum_{r=m}^{\infty} \prod_{p=0}^{r} A_{j-p-1} \sum_{r^{*}>r}^{\infty} \prod_{p=0}^{r^{*}} A_{j-p-1}\right)\right)^{1 / 2}$
$+\omega^{2} E^{1 / 4}\left(\varepsilon_{0}^{8}\right) E^{1 / 4}\left(\begin{array}{c}\sum_{r=0}^{m-k^{*}-1} \prod_{p=0}^{r} A_{j-k^{*}-p-1}^{4} \\ +4 \sum_{r=0}^{m-k^{*}-2} \prod_{p=0}^{r} A_{j-k^{*}-p-1}^{3} \sum_{r^{*}>r-1}^{m-k^{*}-1} \prod_{p=0}^{r^{*}} A_{j-k^{*}-p-1} \\ +6 \sum_{r=0}^{m-k^{*}-2} \prod_{p=0}^{r} A_{j-k^{*}-p-1}^{2}\left(\sum_{r^{*}>r}^{m-k^{*}-1} \prod_{p=0}^{r^{*}} A_{j-k^{*}-p-1}\right)^{2} \\ +4 \sum_{r=0}^{m-k^{*}-2} \prod_{p=0}^{r} A_{j-k^{*}-p-1}\left(\sum_{r^{*}>r}^{m-k^{*}-1} \prod_{p=0}^{r^{*}} A_{j-k^{*}-p-1}\right)^{3}\end{array}\right)$
$\times\left(\sum_{r=m}^{\infty} E\left(\prod_{p=0}^{r} A_{j-p-1}^{2}\right)+2 E\left(\sum_{r=m}^{\infty} \prod_{p=0}^{r} A_{j-p-1} \sum_{r^{*}>r}^{\infty} \prod_{p=0}^{r^{*}} A_{j-p-1}\right)\right)^{1 / 2}$.

Now notice that

$$
\begin{align*}
E\left(\prod_{p=0}^{r} A_{j-p-1} \prod_{p^{*}=0}^{r^{*}} A_{j-p^{*}-1}\right)= & \left(\theta_{2}^{2} E\left(\varepsilon_{0}^{4}\right)+\theta_{3}^{2}+2 \theta_{2} \theta_{3}\right)^{\min \left(r, r^{*}\right)+1}  \tag{13}\\
& \left(\theta_{2}+\theta_{3}\right)^{\max \left(r, r^{*}\right)-\min \left(r, r^{*}\right)} \\
E\left(\prod_{p=0}^{r} A_{j-p-1}^{3} \prod_{p=0}^{r^{*}} A_{j-p-1}\right)= & {\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{4}\right]^{\min \left(r, r^{*}\right)+1} }  \tag{14}\\
& {\left[\begin{array}{c}
{\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{3}\right]^{\max \left(r, r^{*}\right)-\min \left(r, r^{*}\right)} I\left(r>r^{*}\right)} \\
+\left(\theta_{2}+\theta_{3}\right)^{\max \left(r, r^{*}\right)-\min \left(r, r^{*}\right)} I\left(r \leq r^{*}\right)
\end{array}\right] }
\end{align*}
$$

where $I(\cdot)$ is the indicator function. Furthermore, for $r<r^{*}<r^{* *}$ we have that

$$
\begin{aligned}
E\left(\prod_{p=0}^{r} A_{j-p-1}^{2} \prod_{p=0}^{r^{*}} A_{j-p-1}^{2}\right)= & {\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{4}\right]^{r+1}\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{2}\right]^{r^{*}-r}(15) } \\
E\left(\prod_{p=0}^{r} A_{j-p-1} \prod_{p=0}^{r^{*}} A_{j-p-1}^{3}\right)= & {\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{4}\right]^{r+1}\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{3}\right]^{r^{*}-r}(16) } \\
E\left(\prod_{p=0}^{r} A_{j-p-1}^{2} \prod_{p=0}^{r^{*}} A_{j-p-1} \prod_{p=0}^{r^{* *}} A_{j-p-1}\right)= & {\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{4}\right]^{r+1} } \\
& {\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{2}\right]^{r^{*}-r}\left(\theta_{2}+\theta_{3}\right)^{r^{* *}-r^{*}}, } \\
E\left(\prod_{p=0}^{r} A_{j-p-1} \prod_{p=0}^{r^{*}} A_{j-p-1}^{2} \prod_{p=0}^{r^{* *}} A_{j-p-1}\right)= & {\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{4}\right]^{r+1} } \\
& {\left[E\left(\theta_{2}\left|\varepsilon_{0}\right|^{2}+\theta_{3}\right)^{3}\right]^{r^{*}-r}\left(\theta_{2}+\theta_{3}\right)^{r^{* *}-r^{*}}, } \\
E\left(\prod_{p=0}^{r} A_{j-p-1} \prod_{p=0}^{r^{*}} A_{j-p-1} \prod_{p=0}^{r^{* *}} A_{j-p-1}^{2}\right)= & {\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{4}\right]^{r+1} } \\
& {\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{3}\right]^{r^{*}-r}\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{2}\right]^{r^{* *}-r^{*}} }
\end{aligned}
$$

and for $r<r^{*}<r^{* *}<r^{* * *}$ and $\prod\left(r, r^{*}, r^{* *}, r^{* * *}\right)=\prod_{p=0}^{r} A_{j-p-1} \prod_{p^{*}=0}^{r^{*}} A_{j-p^{*}-1} \prod_{p^{* *}=0}^{r^{* *}} A_{j-p^{* *}-1} \prod_{p^{* * *}=0}^{r^{* * *}} A_{j-p-1}$

$$
\begin{align*}
E\left(\prod\left(r, r^{*}, r^{* *}, r^{* * *}\right)\right)= & {\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{4}\right]^{r+1}\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{3}\right]^{r^{*}-r} }  \tag{20}\\
& {\left[E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{2}\right]^{r^{* *}-r^{*}}\left(\theta_{2}+\theta_{3}\right)^{r^{* * *}-r^{* *}} }
\end{align*}
$$

To manage the length of various expressions, let us define $\underline{\eta}_{1}=\underline{\eta}_{\alpha}+\underline{\eta}_{\beta}$, $\bar{\eta}_{1}=\bar{\eta}_{\alpha}+\bar{\eta}_{\beta}, \bar{\eta}_{2}=\bar{\eta}_{\alpha}^{2} E\left(\varepsilon_{0}^{4}\right)+\bar{\eta}_{\beta}^{2}+2 \bar{\eta}_{\alpha} \bar{\eta}_{\beta}, \underline{\eta}_{3}=E\left(\underline{\eta}_{\alpha} \varepsilon_{0}^{2}+\underline{\eta}_{\beta}\right)^{\overline{3}^{\alpha}}, \bar{\eta}_{3}=$ $E\left(\bar{\eta}_{\alpha} \varepsilon_{0}^{2}+\bar{\eta}_{\beta}\right)^{3}, \underline{\eta}_{4}=E\left(\underline{\eta}_{\alpha} \varepsilon_{0}^{2}+\underline{\eta}_{\beta}\right)^{4}, \bar{\eta}_{4}=E\left(\bar{\eta}_{\alpha} \varepsilon_{0}^{2}+\underline{\eta}_{\beta}\right)^{4}$, and for $i, j=$
$2,3,4 \bar{\eta}_{i, j}=\max _{\theta_{2}, \theta_{3}} \frac{1}{E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{i}-E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{j}}$ and $\bar{\eta}_{i, 1}=\max _{\theta_{2}, \theta_{3}} \frac{1}{E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{i}-\left(\theta_{2}+\theta_{3}\right)}$.
Then by repeated applications of equations 13320 we have that
$\omega^{2} E^{1 / 4}\left(\varepsilon_{0}^{8}\right) E^{1 / 4}\left(\sum_{r=0}^{m-k^{*}-1} \prod_{p=0}^{r} A_{j-k^{*}-p-1}^{4}\right)$
$\leq \omega^{2} E^{1 / 4}\left(\varepsilon_{0}^{8}\right)\left(\frac{\bar{\eta}_{4}}{1-\bar{\eta}_{4}}\right)^{1 / 4}=\omega^{2} E^{1 / 4}\left(\varepsilon_{0}^{8}\right) P_{1}^{1 / 4}$, where $P_{1}=\frac{\bar{\eta}_{4}}{1-\bar{\eta}_{4}}$,
and $\omega^{2} E^{1 / 4}\left(\varepsilon_{0}^{8}\right) E^{1 / 4}\left(4 \sum_{r=0}^{m-k^{*}-2} \prod_{p=0}^{r} A_{j-k^{*}-p-1}^{3} \sum_{r^{*}>r}^{m-k^{*}-1} \prod_{p=0}^{r^{*}} A_{j-k^{*}-p-1}\right)$
$\leq \omega^{2} E^{1 / 4}\left(\varepsilon_{0}^{8}\right) P_{2}^{1 / 4}$ where $P_{2}=4 \frac{\bar{\eta}_{1}}{1-\bar{\eta}_{1}}\left[\frac{1}{1-\bar{\eta}_{4}}+\bar{\eta}_{4,1}\right]$.
Further
$\omega^{2} E^{1 / 4}\left(\varepsilon_{0}^{8}\right) E^{1 / 4}\left(6 \sum_{r=0}^{m-k^{*}-2} \prod_{p=0}^{r} A_{j-k^{*}-p-1}^{2}\left(\sum_{r^{*}>r}^{m-k^{*}-1} \prod_{p=0}^{r^{*}} A_{j-k^{*}-p-1}\right)^{2}\right) \leq$ $\omega^{2} E^{1 / 4}\left(\varepsilon_{0}^{8}\right) P_{3}^{1 / 4}$,
where $P_{3}=6 \bar{\eta}_{4} \frac{1}{1-\bar{\eta}_{4}}+6 \frac{\bar{\eta}_{2}^{2}}{1-\bar{\eta}_{2}} \bar{\eta}_{4} \bar{\eta}_{4,2}+12 \frac{\bar{\eta}_{1}}{1-\bar{\eta}_{1}} \frac{\bar{\eta}_{2}}{1-\bar{\eta}_{2}} \frac{\bar{\eta}_{4}}{1-\bar{\eta}_{4}}$
$+12 \frac{\bar{\eta}_{1}}{1-\overline{\bar{\eta}}_{1}} \frac{1}{1-\bar{\eta}_{2}} \bar{\eta}_{4,2}+12 \frac{\bar{\eta}_{1}^{2}}{1-\bar{\eta}_{1}} \bar{\eta}_{2,1} \bar{\eta}_{4,1}$
$+12 \frac{\bar{\eta}_{4}}{1-\bar{\eta}_{1}} \bar{\eta}_{2,1} \bar{\eta}_{4,2}$.
Further $\omega^{2} E^{1 / 4}\left(\varepsilon_{0}^{8}\right) E^{1 / 4}\left(4 \sum_{r=0}^{m-k^{*}-2} \prod_{p=0}^{r} A_{j-k^{*}-p-1}\left(\sum_{r^{*}>r}^{m-k^{*}-1} \prod_{p=0}^{r^{*}} A_{j-k^{*}-p-1}\right)^{3}\right) \leq$ $\omega^{2} E^{1 / 4}\left(\varepsilon_{0}^{8}\right) P_{4}$
where $P_{4}=4 \frac{\bar{\eta}_{3} \bar{\eta}_{4}}{1-\bar{\eta}_{3}}\left(1+\frac{1}{1-\bar{\eta}_{4}} \frac{1}{\bar{\eta}_{3}^{*}} \bar{\eta}_{4,3}\right)+12 \frac{\bar{\eta}_{1}}{1-\bar{\eta}_{1}} \frac{\bar{\eta}_{3} \bar{\eta}_{4}}{1-\bar{\eta}_{3}} \frac{1}{1-\bar{\eta}_{4}}$
$+12 \frac{\bar{\eta}_{1}}{1-\bar{\eta}_{1}} \bar{\eta}_{3,1} \bar{\eta}_{1} \bar{\eta}_{4} \bar{\eta}_{4,1} \frac{1}{\eta_{4}^{k^{*}}}+12 \frac{\bar{\eta}_{1}}{1-\bar{\eta}_{1}}\left(\bar{\eta}_{3}+1\right) \frac{\bar{\eta}_{3,1} \bar{\eta}_{4,3}}{\eta_{3}^{k_{3}^{*}}}$
$+12 \frac{\bar{\eta}_{3}}{1-\bar{\eta}_{2}}\left(\bar{\eta}_{2}^{2}+\bar{\eta}_{4}\right) \bar{\eta}_{4,2} \bar{\eta}_{3,2} \frac{1}{\eta_{3}^{k^{*}}}+24 \frac{\bar{\eta}_{1}}{1-\bar{\eta}_{1}} \frac{\bar{\eta}_{2}}{1-\bar{\eta}_{2}} \frac{\frac{3}{\bar{\eta}_{3}}}{1-\bar{\eta}_{3}} \frac{\bar{\eta}_{4}}{1-\bar{\eta}_{4}}$
$+12 \frac{\bar{\eta}_{2}}{1-\bar{\eta}_{2}} \frac{\bar{\eta}_{3} \bar{\eta}_{4}}{1-\bar{\eta}_{3}}\left(\frac{1}{1-\bar{\eta}_{4}}+\bar{\eta}_{4,3} \frac{1}{\underline{\eta}_{3}^{k^{*}}}\right)+24 \frac{\bar{\eta}_{1}}{1-\bar{\eta}_{1}} \frac{1}{1-\bar{\eta}_{2}}\left(\frac{\bar{\eta}_{2}}{1-\bar{\eta}_{3}}+\bar{\eta}_{3,2}\right) \frac{\bar{\eta}_{4} \overline{\bar{n}}_{4,3}}{\underline{\eta}_{3}^{k^{*}+1}}$
$+24 \frac{\bar{\eta}_{\bar{\eta}} \bar{\eta}_{2} \overline{\bar{m}}_{3}}{1-\bar{\eta}_{1}}\left[\bar{\eta}_{2}^{2} \bar{\eta}_{3,2} \bar{\eta}_{4,2} \frac{1}{\underline{\eta}_{4}^{k^{*}+3}}\left(\frac{\bar{\eta}_{2} \bar{\eta}_{4}}{1-\bar{\eta}_{2}}+\bar{\eta}_{1} \bar{\eta}_{2,1}\right)+\bar{\eta}_{1} \bar{\eta}_{2,1} \bar{\eta}_{3,1}\left(\bar{\eta}_{4} \bar{\eta}_{4,1}+\bar{\eta}_{4,3} \frac{1}{\eta_{4}^{k^{*}+2}}\right)\right]$
$+24 \frac{\bar{\eta}_{1}}{1-\bar{\eta}_{1}} \bar{\eta}_{1} \bar{\eta}_{2,1} \bar{\eta}_{2}^{2} \bar{\eta}_{3,2} \frac{1}{\underline{\eta}_{3}^{k^{*}+1}} \bar{\eta}_{4} \bar{\eta}_{4,3}$, and for $i, j=2,3,4 \bar{\eta}_{i, j}=\max _{\theta_{2}, \theta_{3}} \frac{1}{E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{i}-E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{j}}$
and $\bar{\eta}_{i, 1}=\max _{\theta_{2}, \theta_{3}} \frac{1}{E\left(\theta_{2} \varepsilon_{0}^{2}+\theta_{3}\right)^{i}-\left(\theta_{2}+\theta_{3}\right)}$
Finally notice
$\sum_{r=m-k^{*}}^{\infty} E\left(\prod_{p=0}^{r} A_{j-k^{*}-p-1}^{2}\right)+2 \sum_{r^{*}>r=m-k^{*}}^{\infty} E\left(\prod_{p=0}^{r} A_{j-k^{*}-p-1} \prod_{p=0}^{r^{*}} A_{j-k^{*}-p-1}\right)$
$\leq C_{1} \bar{\eta}_{2}^{m}$ where $C_{1}=\left(1+2 \frac{\bar{\eta}_{1}}{1-\bar{\eta}_{1}}\right) \frac{1}{\bar{\eta}_{3}^{k^{*}}} \frac{1}{1-\bar{\eta}_{2}}$.
Hence we have that

$$
\begin{equation*}
E\left|y_{j}^{2} y_{j-k^{*}}^{2}-\omega^{2} \varepsilon_{j}^{2} \varepsilon_{j-k^{*}}^{2} \Omega_{m} \Omega_{m-k^{*}}\right| \leq B \bar{\eta}_{2}^{m / 2} \tag{21}
\end{equation*}
$$

where $B=\bar{\eta}_{\omega}\left(1-\underline{\eta}_{1}\right) E^{1 / 4}\left(\varepsilon_{0}^{8}\right)\left[\begin{array}{c}C_{1}^{1 / 2} \sup E^{1 / 4}\left(h_{0}^{4}\right)+\bar{\eta}_{\omega}\left(1-\underline{\eta}_{1}\right) E^{1 / 4}\left(\varepsilon_{0}^{4}\right) C_{1}^{1 / 2} \bar{\eta}_{2}^{k^{*} / 2} \\ +\left(1-\bar{\eta}_{1}\right)\left(P_{1}^{1 / 4}+4 P_{2}^{1 / 4}+6 P_{3}^{1 / 4}+P_{4}^{1 / 4}\right) C_{1}^{1 / 2} \bar{\eta}_{2}^{k^{*} / 2}\end{array}\right]$.

Finally, for $0<m<k^{*}$ we have that

$$
\begin{aligned}
E\left|y_{j}^{2} y_{j-k^{*}}^{2}-\omega^{2} \varepsilon_{j}^{2} \varepsilon_{j-k^{*}}^{2} \Omega_{m}\right| \leq & \omega^{2} \frac{1}{1-\left(\theta_{2}+\theta_{3}\right)}\left(1+\frac{1}{1-\left(\theta_{2}+\theta_{3}\right)}\right)\left(\theta_{2}+\theta_{3}\right)^{m} \\
& +\left(\theta_{2}+\theta_{3}\right)^{k^{*}-1}\left[\theta_{2} E\left(\varepsilon_{0}^{4}\right)+\theta_{3}\right] E\left(h_{j-k^{*}}^{2}\right) \\
& +\omega\left(1+\frac{1}{1-\left(\theta_{2}+\theta_{3}\right)}\right) E\left(h_{j-k^{*}}\right) \\
& +2 \omega^{2}\left(\theta_{2}+\theta_{3}\right)^{k^{*}-1}\left[\theta_{2} E\left(\varepsilon_{0}^{4}\right)+\theta_{3}\right] .
\end{aligned}
$$

Hence
$E\left|y_{j}^{2} y_{j-k^{*}}^{2}-\omega^{2} \varepsilon_{j}^{2} \varepsilon_{j-k^{*}}^{2} \Omega_{m}\right| \leq\left\{\begin{array}{c}\bar{\eta}_{\omega}^{2}\left(1-\bar{\eta}_{1}\right)\left(1+\frac{1}{1-\bar{\eta}_{1}}\right) \\ +\frac{1}{\bar{\eta}_{1}}\left[\bar{\eta}_{\alpha} \sup E\left(\varepsilon_{0}^{4}\right)+\bar{\eta}_{\beta}\right]\left[\sup E\left(h_{0}^{2}\right)+2 \bar{\eta}_{\omega}^{2}\left(1-\bar{\eta}_{1}\right)^{2}\right] \\ +\frac{\bar{\eta}_{\omega}\left(1-\bar{\eta}_{1}\right)}{\bar{\eta}_{1}^{k^{*}}}\left(1+\frac{1}{1-\bar{\eta}_{1}}\right) \sup E\left(h_{0}\right)\end{array}\right\} \bar{\eta}_{1}^{m}$.
Equations 21 and 22 imply that assumption A.2-WD holds. Now $\frac{\partial y_{j}^{2}}{\partial \varepsilon_{j-m}^{2}}$ equals

$$
\left\{\begin{array}{c}
h_{j} \text { when } m=0  \tag{23}\\
\varepsilon_{j}^{2} \omega \theta_{2} \sum_{r=m-1}^{\infty} \prod_{p=0}^{r-\{m-1\}}\left(\theta_{2} \varepsilon_{j-p-1}^{2}+\theta_{3}\right) \text { when } m>0
\end{array}\right.
$$

$\frac{\partial y_{j}^{4}}{\partial \varepsilon_{j-m}^{2}}$ equals

$$
\left\{\begin{array}{c}
2 \varepsilon_{j}^{2} h_{j}^{2} \text { when } m=0  \tag{24}\\
2 \theta_{2} \omega \varepsilon_{j}^{4} h_{j}\left(\sum_{r=m-1}^{\infty} \prod_{p=0}^{j-\{m-1\}}\left(\theta_{2} \varepsilon_{j-p-1}^{2}+\theta_{3}\right)\right) \text { when } m>0
\end{array}\right.
$$

and for any $k^{*}>0, \frac{\partial y_{j}^{2} y_{j-k^{*}}^{2}}{\partial \varepsilon_{j-m}^{2}}$ equals

$$
\left\{\begin{array}{c}
\varepsilon_{j-k^{*}}^{2} h_{j} h_{j-k^{*}} \text { when } m=0  \tag{25}\\
\omega \varepsilon_{j}^{2} \varepsilon_{j-k^{*}}^{2} \theta_{2}\left(\sum_{r=m-1}^{\infty} \prod_{p=0}^{r-\{m-1\}}\left(\theta_{2} \varepsilon_{j-p-1}^{2}+\theta_{3}\right)\right) h_{j-k^{*}} \text { when } 0<m<k^{*} \\
\varepsilon_{j}^{2} h_{j} h_{j-k^{*}}+\omega \varepsilon_{j}^{2} \varepsilon_{j-k^{*}}^{2} \theta_{2}\left(\sum_{r=k^{*}-1}^{\infty} \prod_{p=\left\{k^{*}-1\right\}}^{r-\left\{k^{*}\right.}\left(\theta_{2} \varepsilon_{j-p-1}^{2}+\theta_{3}\right)\right) h_{j-k^{*}} \text { when } m=k^{*} . \\
\omega^{2} \varepsilon_{j}^{2} \varepsilon_{j-k^{*}}^{2} \theta_{2}\binom{h_{j-k^{*}} \sum_{r=m-1}^{\infty} \prod_{p=0}^{r-\{m-1\}}\left(\theta_{2} \varepsilon_{j-p-1}^{2}+\theta_{3}\right)}{+h_{j} \sum_{r=m+k^{*}-1}^{\infty} \prod_{p=0}^{r-\{m-1\}}\left(\theta_{2} \varepsilon_{j-k^{*}-p-1}^{\infty}+\theta_{3}\right)} \text { when } m>k^{*}
\end{array}\right.
$$

Hence

$$
E\left|\frac{\partial y_{j}^{2}}{\partial \varepsilon_{0}^{2}}\right| \leq\left\{\begin{array}{c}
\bar{\eta}_{\omega} \text { when } j=0 \\
\frac{\bar{\eta}_{\omega} \bar{\eta}_{\alpha}}{\bar{\eta}_{\alpha}+\bar{\eta}_{\beta}}\left(\bar{\eta}_{\alpha}+\bar{\eta}_{\beta}\right)^{j} \text { when } j>0
\end{array}\right.
$$

$$
\begin{gathered}
E\left|\frac{\partial y_{j}^{4}}{\partial \varepsilon_{0}^{2}}\right| \leq\left\{\begin{array}{c}
2 \bar{\eta}_{\omega}^{2} \frac{1}{1-\bar{\eta}_{2}} \text { when } j=0 \\
2 \bar{\eta}_{\alpha} \theta_{2} \bar{\eta}_{\omega}^{2}\left(1-\underline{\eta}_{\alpha}-\underline{\eta}_{\beta}\right) \sup E\left(\varepsilon_{0}^{4}\right) \bar{\eta}_{1}^{j-1}+ \\
2 \theta_{2} \bar{\eta}_{\omega}^{2}\left(1-\underline{\eta}_{\alpha}-\underline{\eta}_{\beta}\right)^{2} \sup E\left(\varepsilon_{0}^{4}\right) \frac{2+\bar{\eta}_{1}}{1-\bar{\eta}_{2}} \bar{\eta}_{2,1} \bar{\eta}_{2}^{j} \text { when } j>0
\end{array}\right. \\
E\left|\frac{\partial y_{j}^{2} y_{j-k^{*}}^{2}}{\partial \varepsilon_{0}^{2}}\right| \leq\left\{\begin{array}{c}
\sup _{\theta \in \Theta} E\left(h_{0} \varepsilon_{-k^{*}}^{2} h_{-k^{*}}\right) \text { when } j=0 \\
\bar{\eta}_{\omega}^{2} \bar{\eta}_{\alpha}\left(1+\frac{\bar{\eta}_{2}}{1-\bar{\eta}_{2}}\right) \bar{\eta}_{1}^{j-1} \text { when } 0<j<k^{*} \\
\sup _{\theta \in \Theta} E\left(h_{j} h_{j-k^{*}}\right)+\bar{\eta}_{\alpha} \bar{\eta}_{\omega} \frac{\left(\bar{\eta}_{\alpha}+\bar{\eta}_{\beta}\right)^{j-1}}{1-\bar{\eta}_{2}} \text { when } j=k^{*} \\
\bar{\eta}_{\omega}^{3} \bar{\eta}_{\alpha}\left(C_{1} \bar{\eta}_{1}^{j}+C_{2} \bar{\eta}_{2}^{j}+C_{3} \bar{\eta}_{2}^{j}+C_{4} \bar{\eta}_{2}^{j}+C_{5} \bar{\eta}_{2}^{2 j}\right) \text { when } j>k^{*}
\end{array}\right.
\end{gathered}
$$

where $C_{1}=2 \frac{\bar{\eta}_{\alpha} \sup E\left(\varepsilon_{0}^{4}\right)+\theta_{3}}{\left(\underline{\eta}_{\alpha}+\underline{\eta}_{\beta}\right)^{2}}+\frac{\bar{\eta}_{\alpha} \sup E\left(\varepsilon_{0}^{4}\right)+\bar{\eta}_{\beta}}{\left(\underline{\eta}_{\alpha}+\underline{\eta}_{\beta}\right)}+\frac{1}{1-\bar{\eta}_{1}}+\bar{\eta}_{\alpha} \sup E\left(\varepsilon_{0}^{4}\right)+\bar{\eta}_{\beta}, C_{2}=$ $\frac{\bar{\eta}_{\alpha} \sup E\left(\varepsilon_{\varepsilon^{4}}^{4}\right)+\bar{\eta}_{\beta}}{\underline{\eta}_{2}^{k^{*}}}\left[\frac{1}{\underline{\eta}_{2}-\bar{\eta}_{1}}+\frac{1}{\underline{\eta}_{2}}\right], C_{3}=\frac{\bar{\eta}_{\alpha} \sup E\left(\varepsilon_{0}^{4}\right)+\bar{\eta}_{\beta}}{\underline{\eta}_{2}}\left[2+\frac{3}{1-\bar{\eta}_{2}}+\bar{\eta}_{2,1}\right]$,
$C_{4}=\left(\bar{\eta}_{\alpha} \sup E\left(\varepsilon_{0}^{4}\right)+\bar{\eta}_{\beta}\right) \bar{\eta}_{2,1}\left(\frac{1}{\underline{\eta}_{2}}+\frac{1}{\underline{\eta}_{2}^{k^{*}}} \frac{1}{1-\bar{\eta}_{2}}\right)$ and $C_{5}=2 \frac{\bar{\eta}_{\alpha} \sup E\left(\varepsilon_{0}^{4}\right)+\bar{\eta}_{\beta}}{\underline{\eta}_{2}^{k^{*}}} \frac{1}{1-\bar{\eta}_{2}}$.
Notice that these do not necessarily imply condition 2.3.(i) in page 2073 of Gotze and Hipp [9]. In fact this condition does not apply in our case. However, they imply assumption A.3-EL. The form of 2325 imply condition A.2.CPD. Finally notice that $23+25$ imply

$$
\begin{gather*}
\sum_{j=0}^{\infty} \frac{\partial y_{j}^{2}}{\partial \varepsilon_{0}^{2}}=h_{0}+\sum_{j=1}^{\infty} \varepsilon_{j}^{2} \frac{\partial h_{j}}{\partial \varepsilon_{0}^{2}}  \tag{26}\\
\sum_{j=0}^{\infty} \frac{\partial y_{j}^{4}}{\partial \varepsilon_{0}^{2}}=2 \varepsilon_{0}^{2} h_{0}+2 \sum_{j=1}^{\infty} \varepsilon_{j}^{4} h_{j} \frac{\partial h_{j}}{\partial \varepsilon_{0}^{2}} \tag{27}
\end{gather*}
$$

$$
\begin{align*}
\sum_{j=0}^{\infty} \frac{\partial y_{j}^{2} y_{j-1}^{2}}{\partial \varepsilon_{0}^{2}}= & \varepsilon_{-1}^{2} h_{0} h_{-1}+\varepsilon_{1}^{2} h_{1} h_{0}+\varepsilon_{1}^{2} \varepsilon_{0}^{2} \frac{\partial h_{1}}{\partial \varepsilon_{0}^{2}} h_{0}  \tag{28}\\
& +\sum_{j=1}^{\infty} \varepsilon_{j}^{2} \varepsilon_{j-1}^{2}\left(\frac{\partial h_{j}}{\partial \varepsilon_{0}^{2}} h_{j-1}+\frac{\partial h_{j-1}}{\partial \varepsilon_{0}^{2}} h_{j}\right)
\end{align*}
$$

and

$$
\begin{align*}
\sum_{j=0}^{\infty} \frac{\partial y_{j}^{2} y_{j-2}^{2}}{\partial \varepsilon_{0}^{2}}= & \varepsilon_{-2}^{2} h_{0} h_{-2}+\varepsilon_{2}^{2} h_{2} h_{0}+\varepsilon_{1}^{2} \varepsilon_{-1}^{2} \frac{\partial h_{1}}{\partial \varepsilon_{0}^{2}} h_{-1}+\varepsilon_{2}^{2} \varepsilon_{0}^{2} \frac{\partial h_{2}}{\partial \varepsilon_{0}^{2}} h_{0}(  \tag{29}\\
& +\sum_{j=1}^{\infty} \varepsilon_{j}^{2} \varepsilon_{j-2}^{2}\left(\frac{\partial h_{j}}{\partial \varepsilon_{0}^{2}} h_{j-2}+\frac{\partial h_{j-2}}{\partial \varepsilon_{0}^{2}} h_{j}\right)
\end{align*}
$$

and that the right hand sides of $26-28$ are series of polynomial functions of $\left(\varepsilon^{2}\right)$, hence are linearly dependent iff there exist $\lambda_{i}, i=1, \ldots, 4$ that are
independent of $j$ such that the relevant linear combinations of the coefficients of the terms of the same monomials are zero for every $j$. A simple inspection reveals that this is impossible for $P$ almost all $\left(\varepsilon^{2}\right)$ and for all $\theta \in \Theta$. This in turn implies that the determinant of the matrix

$$
\sum_{j=0}^{\infty}\left(\frac{\partial y_{j}^{2}}{\partial \varepsilon_{l_{i}}^{2}} \frac{\partial y_{j}^{4}}{\partial \varepsilon_{l_{i}}^{2}} \frac{\partial y_{j}^{2} y_{j-1}^{2}}{\partial \varepsilon_{l_{i}}^{2}} \quad \frac{\partial y_{j}^{2} y_{j-2}^{2}}{\partial \varepsilon_{l_{i}}^{2}}, i=1, \ldots, 4\right)
$$

with distinct $l_{i}$ where $0=l_{i}$ for some $i$ is different from zero for all $\theta \in \Theta$. This along with the continuity of these four terms on $\Theta$ the continuity of the determinant and the compactness of $\Theta$ imply that condition A.2-NDD holds. Finally lemma 2.6 and theorem 2.1 yield the result.

Let

$$
b(\theta)=\left(\theta_{1}, \frac{\theta_{2}\left(1-\left(\theta_{2}+\theta_{3}\right) \theta_{3}\right)}{1-2 \theta_{2} \theta_{3}-\theta_{3}^{2}}, \theta_{2}+\theta_{3}\right)^{\prime}
$$

and for some compact $B \supseteq b(\Theta)$ define

$$
\varphi_{n} \in \arg \min _{\varphi \in B} \frac{1}{2}\left\|\left(\overline{y^{2}}, \widehat{\rho_{1}}, \frac{\widehat{\rho_{2}}}{\widehat{\rho_{1}}}\right)^{\prime}-\varphi\right\|^{2}
$$

where $\overline{y^{2}}=\frac{1}{n} \sum_{j=1}^{n} y_{j}^{2}, \widehat{\rho}_{i}=\frac{\frac{1}{n} \sum_{j=1}^{n}\left(y_{t}^{2} y_{t-i}^{2}\right)-\left(\overline{y^{2}}\right)^{2}}{\frac{1}{n} \sum_{j=1}^{n}\left(y_{t}^{4}\right)-\left(\overline{y^{2}}\right)^{2}}$. Furthermore define

$$
\theta_{n} \in \arg \min _{\theta \in \Theta} \frac{1}{2}\left\|\varphi_{n}-b(\theta)\right\|^{2}
$$

It is easy to see that due to the joint measurability, continuity and boundness from below of the criteria, $\varphi_{n}$ and $\theta_{n}$ exist (see for example Theorem 2.13 of Molchanov [12]). $\theta_{n}$ essentially corresponds to the definition of the first of the indirect estimators in Gourieroux et. al. [10]. For any compact $\Theta^{\prime} \subset \operatorname{Int}(\Theta)$ we obtain the following proposition.

Proposition 2 Under assumption A.5 $\sqrt{n}\left(\varphi_{n}-b(\theta)\right)$ and $\sqrt{n}\left(\theta_{n}-\theta\right)$ admit locally uniform Edgeworth expansions of order s-2 over $\Theta^{\prime}$, the polynomials of the density of which satisfy assumption A.4-EEQ.

Proof. Let us define the function $f(x)=\left(x_{1}, \frac{x_{3}-x_{1}^{2}}{x_{2}-x_{1}^{2}}, \frac{x_{4}-x_{1}^{2}}{x_{2}-x_{1}^{2}}\right)$ which is continuous. A Taylor expansion of $f$-which is independent of $\theta$ - around $E\left(X_{0}(\theta)\right)$ of order $s-1$ implies that ( $S_{n}$ is as in proposition 1 )
$\sqrt{n}\left(\left(\overline{y^{2}}, \widehat{\rho_{1}}, \frac{\widehat{\rho_{2}}}{\widehat{\rho}_{1}}\right)^{\prime}-b(\theta)\right)=\sum_{i=0}^{s-2} \frac{1}{n^{i / 2}} D^{(i+1)} f\left(E\left(X_{0}(\theta)\right)\right)\left(S_{n}(\theta)\right)^{i+1}+R_{n}(\theta)$
where
$R_{n}(\theta)=\frac{1}{n^{(s-2) / 2}}\left(D^{(s-1)} f\left(R_{n}^{+}(\theta)\right)\left(S_{n}(\theta)\right)^{s-1}-D^{(s-1)} f\left(E\left(X_{0}(\theta)\right)\right)\left(S_{n}(\theta)\right)^{s-1}\right)$
$R_{n}^{+}(\theta)$ lies between $\frac{1}{n} \sum_{j=1}^{n} X_{j}(\theta)$ and $E\left(X_{0}(\theta)\right)$ with probability $1-o\left(n^{-\frac{s-2}{2}}\right)$ that does not depend on $\theta$. Due to the continuity of $D^{(s-1)} f$ on some compact neighborhood of $E\left(X_{0}(\theta)\right)$ we have that

$$
\left\|R_{n}(\theta)\right\| \leq \frac{\left\|R_{n}^{+}(\theta)\right\|\left\|S_{n}(\theta)\right\|^{s-1}}{n^{(s-2) / 2}}
$$

Hence the definition of $R_{n}^{+}(\theta)$, along with proposition 1, lemma AL.2, and theorem 3.3 imply that the result will hold if $\sum_{i=0}^{s-2} \frac{1}{n^{i / 2}} D^{\overrightarrow{(i+1)}} f\left(E\left(X_{0}(\theta)\right)\right)\left(S_{n}(\theta)\right)^{i+1}$ admits the relevant Edgeworth expansion. But this holds due to the fact that $D f\left(E\left(X_{0}(\theta)\right)\right)$ has rank 3 for any $\theta$ hence assumption A.3-POL is satisfied, while assumption A.3-EEQ is satisfied due to proposition 1, hence theorem 3.1 is applicable. Notice now that with probability $1-o\left(n^{-\frac{s-2}{2}}\right)$ that does not locally depend on $\theta, \varphi_{n}=\left(\overline{y^{2}}, \widehat{\rho_{1}}, \frac{\widehat{\rho_{2}}}{\rho_{1}}\right)^{\prime}$. Hence due to theorem 3.3 the first result follow as $\sqrt{n}\left(\left(\overline{y^{2}}, \widehat{\rho_{1}}, \frac{\widehat{\rho_{2}}}{\widehat{\rho}_{1}}\right)^{\prime}-b(\theta)\right)$ admits a locally uniform Edgeworth expansion of order s-2 over $\Theta^{\prime}$ (in the notation of the theorem $S_{n}=\sqrt{n}\left(\left(\overline{y^{2}}, \widehat{\rho_{1}}, \frac{\widehat{\rho_{2}}}{\rho_{1}}\right)^{\prime}-b(\theta)\right)$ and $R_{n}$ is zero).
For $\sqrt{n}\left(\theta_{n}-\theta\right)$ initially observe that due to the first part, for some $\Theta^{*}=$ $\left[\underline{\eta}_{\omega}^{*}, \bar{\eta}_{\omega}^{*}\right] \times\left[\underline{\eta}_{\alpha}^{*}, \bar{\eta}_{\alpha}^{*}\right] \times\left[\underline{\eta}_{\beta}^{*}, \bar{\eta}_{\beta}^{*}\right]$ where $0<\underline{\eta}_{m}^{*}<\underline{\eta}_{m}, \bar{\eta}_{m}^{*}>\bar{\eta}_{m}$ for $m=\omega, \alpha, \beta$, such that $\operatorname{Int}(\Theta) \supset \Theta^{*} \supset \Theta^{\prime}$

$$
\sup _{\theta \in \overline{\mathcal{O}}\left(\theta_{0}, \delta\right)} P\left(\varphi_{n}(\theta) \in \overline{\mathcal{O}}\left(\theta_{0}, \delta^{*}\right)\right)=1-o\left(n^{-\frac{s-2}{2}}\right)
$$

and it is easy to see that $\frac{\partial b}{\partial \theta^{\prime}}$ has full rank for any $\theta$ in $\overline{\mathcal{O}}\left(\theta_{0}, \delta^{*}\right)$, hence with probability $1-o\left(n^{-\frac{s-2}{2}}\right)$ that does not locally depend on $\theta, \theta_{n}$ satisfies $\varphi_{n}=b\left(\theta_{n}\right)$. The mean value theorem along with the constant full rank and continuity of $\frac{\partial b}{\partial \theta^{\prime}}$ on $\Theta^{\prime}$ imply that for some $c>0$ independent of $\theta$

$$
\sup _{\theta \in \overline{\mathcal{O}}\left(\theta_{0}, \delta\right)} P\left(\sqrt{n}\left\|\theta_{n}-\theta\right\| \leq c \sqrt{n}\left\|\varphi_{n}-b(\theta)\right\|\right)=1-o\left(n^{-\frac{s-2}{2}}\right)
$$

which along with the result of the first part and lemma AL. 2 imply that for some $C^{*}>0$ independent of $\theta$

$$
\begin{equation*}
\sup _{\theta \in \overline{\mathcal{O}}\left(\theta_{0}, \delta\right)} P\left(\sqrt{n}\left\|\theta_{n}-\theta\right\|>C^{*} \ln ^{1 / 2} n\right)=o\left(n^{-\frac{s-2}{2}}\right) \tag{30}
\end{equation*}
$$

A Taylor expansion of $b\left(\theta_{n}\right)$ around $b(\theta)$ of order $s-1$ implies that $\left(S_{n}\right.$ is as in proposition 1)
$0_{3 \times 1}=\sqrt{n}\left(\varphi_{n}-b(\theta)\right)+\sqrt{n} \sum_{i=0}^{s-2} \frac{1}{n^{i / 2}} D^{(i+1)} b(\theta)\left(\sqrt{n}\left(\theta_{n}-\theta\right)\right)^{i+1}+R_{n}(\theta)$
where
$R_{n}(\theta)=\frac{1}{n^{(s-2) / 2}}\left(D^{(s-1)} b\left(\theta_{n}^{+}\right)\left(\sqrt{n}\left(\theta_{n}-\theta\right)\right)^{s-1}-D^{(s-1)} b(\theta)\left(\sqrt{n}\left(\theta_{n}-\theta\right)\right)^{s-1}\right)$
$\theta_{n}^{+}$lies between $\theta_{n}$ and $\theta$ with probability $1-o\left(n^{-\frac{s-2}{2}}\right)$ that does not depend on $\theta$. Due to the continuity of $D^{(s-1)} b$ on some compact neighborhood of $\theta$ we have that

$$
\left\|R_{n}(\theta)\right\| \leq \frac{\left\|\theta_{n}^{+}-\theta\right\|\left\|\sqrt{n}\left(\theta_{n}-\theta\right)\right\|^{s-1}}{n^{(s-2) / 2}}
$$

Hence the definition of $\theta_{n}^{+}$, along with proposition 2, equation 30, and theorem 3.3 imply that the result will hold if condition POLFOC holds since in this case theorem 3.2 is applicable. But this holds due to the constant full rank of the Jacobian of $b$.

For the final part of this section we utilize the following assumption.
Assumption A. $6 s \geq 5$ and $\varepsilon_{0} \sim N(0,1)$.
Remember that $\varphi_{n}$ and $\theta_{n}$ depend on $X_{i}$ which in turn depends on $\theta$. When needed this dependence will be explicitly denoted. Define

$$
\varphi_{n}^{*} \in \arg \min _{\theta \in \Theta} \frac{1}{2}\left\|\varphi_{n}-E\left(\varphi_{n}(\theta)\right)\right\|^{2}
$$

and

$$
\theta_{n}^{*} \in \arg \min _{\theta \in \Theta} \frac{1}{2}\left\|\theta_{n}-E\left(\theta_{n}(\theta)\right)\right\|^{2}
$$

These correspond to the definition of the second of the indirect estimators in Gourieroux et. al. [10]. The boundness of $B$ and $\Theta$ imply that the relevant expectations exist for any $\theta$. The $P$ almost everywhere continuity of $X_{i}$ w.r.t. $\theta$ along with the definitions of $\varphi_{n}$ and $\theta_{n}$ and the boundness of $B$ and $\Theta$ ensure via the dominated convergence theorem that the expectations are also continuous and this along with joint measurability and the boundness from below of the criteria imply again the existence of $\varphi_{n}^{*}$ and $\theta_{n}^{*}$. Similarly to the previous case we obtain the following proposition.

Proposition 3 Suppose that $\sqrt{n}\left(\varphi_{n}-b(\theta)\right)$ and $\sqrt{n}\left(\theta_{n}-\theta\right)$ admit locally uniform Edgeworth expansions of order $s-2$ over $\Theta^{\prime}$ the polynomials of the densities of which satisfy assumption A.4-EEQ and A.6 holds. Then $\sqrt{n}\left(\varphi_{n}^{*}-\theta\right)$ and $\sqrt{n}\left(\theta_{n}^{*}-\theta\right)$ admit locally uniform Edgeworth expansions of order $s-3$ over $\Theta^{\prime \prime}$ for any compact $\Theta^{\prime \prime} \subset \Theta^{\prime}$.

For the proof of the previous proposition we use the following auxiliary results. In the following lemma $m_{n}(\theta)$ denotes a generic random vector some elements of which admit values in a bounded subset of some Euclidean space.

Lemma 4.1 Suppose that $\sqrt{n} m_{n}(\theta)$ admits a locally uniform Edgeworth expansion of order $s-2$ over $\Theta^{\prime}$, the polynomials of the density of which satisfy assumption A.4 EEQ. Let the random element $\sqrt{n} \gamma_{n}(\theta)$ be comprised by elements of $\sqrt{n m_{n}}(\theta)$ such that its support is bounded by $\sqrt{n} \Gamma$ for $\Gamma$ a bounded set of some Euclidean space. Then $\sqrt{n} m_{n}^{*}(\theta)=\sqrt{n}\binom{m_{n}(\theta)}{\gamma_{n}(\theta)-E \gamma_{n}(\theta)}$ admits a locally uniform Edgeworth expansion of order $s-3$ over $\overline{\mathcal{O}}\left(\theta_{0}, \delta\right)$, the polynomials of the density of which satisfy assumption A.4-EEQ.

Proof. Lemma AL. 1 implies that $\sqrt{n} \gamma_{n}(\theta)$ admits a locally uniform Edgeworth expansion of order $s-2$ over $\Theta^{\prime}$, the polynomials of the density of which satisfy assumption A.4-EEQ. Due to Lemma 3.1 of Arvanitis and Demos [1] we have that

$$
\begin{aligned}
& \sup _{\theta \in \Theta^{\prime}}\left|\sqrt{n} E_{\theta} \gamma_{n}-\int_{\mathbb{R}} z\left(1+\sum_{i=1}^{s-3} \frac{\pi_{i}(z, \theta)}{n^{(i+1) / 2}}\right) \varphi_{V(\theta)}(z) d z\right| \\
= & \sup _{\theta \in \Theta^{\prime}}\left|\sqrt{n} E_{\theta} \gamma_{n}-\sum_{i=1}^{s-3} \frac{\mathcal{I}_{V}\left(k_{i}(z, \theta)\right)}{n^{i / 2}}\right|=o\left(n^{-\frac{s-3}{2}}\right)
\end{aligned}
$$

where $\left(1+\sum_{i=1}^{s-3} \frac{\pi_{i}(z, \theta)}{n^{i / 2}}\right) \varphi_{V(\theta)}(z)$ denotes the density of the Edgeworth distribution of proposition 2 truncated up to the $O\left(n^{-\frac{s-3}{2}}\right)$ order, i.e. of the (obviously) valid locally uniform Edgeworth expansion of order $s-3$, given the one in 2, $k_{i}(z, \theta)=z \pi_{i}(z, \theta)$ and $\mathcal{I}_{V}\left(k_{i}(z, \theta)\right)=\int_{\mathbb{R}} k_{i}(z, \theta) \varphi_{V(\theta)}(z) d z$. Using the fact that the $\pi_{i}$ 's satisfy assumption A.4-EEQ it is easy to see that so do the $\mathcal{I}_{V}\left(k_{i}(z, \theta)\right)$. It is also obvious that the random vector $\sqrt{n} l_{n}(\theta)=\sqrt{n}\binom{m_{n}(\theta)}{\gamma_{n}(\theta)}$ admits a locally uniform Edgeworth expansion of order $s-2$ over $\Theta^{\prime}$, the polynomials of the density (say $\pi_{i}^{*}$ ) of which satisfy assumption A.4-EEQ. Consider the vector $v_{n}=\binom{0_{\operatorname{dim}\left(m_{n}\right)}^{\sum_{\text {a }}}}{\sum_{i=1}^{s-3} \frac{I_{V}\left(k_{i}(z, \theta)\right)}{n^{i / 2}}}$.

For an arbitrary Borel set $A$ due to the previous

$$
\begin{aligned}
& P\left(\sqrt{n} m_{n}^{*}(\theta) \in A\right) \\
= & P\left(\sqrt{n} l_{n}(\theta) \in A+v_{n}+o\left(n^{-\frac{s-3}{2}}\right)\right) \\
= & \int_{A \cap \mathcal{H}_{n}^{c}(C)}\left(1+\sum_{i=1}^{s-3} \frac{\pi_{i}^{*}\left(z+\binom{0_{\operatorname{dim}\left(m_{n}\right)}}{\sum_{i=1}^{s-3} \frac{\mathcal{I}_{V}\left(k_{k}(z, \theta)\right)}{n^{i / 2}}}+o\left(n^{-\frac{s-3}{2}}\right), \theta\right)}{n^{i / 2}}\right) \\
& \times \varphi_{V(\theta)}\left(z+\binom{0_{\operatorname{dim}\left(m_{n}\right)}^{s-3} \mathcal{I}_{V}\left(k_{i}(z, \theta)\right)}{n_{i=1}^{s i / 2}}+o\left(n^{-\frac{s-3}{2}}\right)\right) d z+o\left(n^{-\frac{s-3}{2}}\right)
\end{aligned}
$$

where $\mathcal{H}_{n}^{c}(C)$ analogously to the relevant term in the proof of theorem 3.1 . Expanding and holding terms of relevant order, by noticing that the $\pi_{i}$ are polynomial in $z$, and that the $o\left(n^{-\frac{s-2}{2}}\right)$ are independent of $\theta$ we obtain the needed result.

The second auxiliary result is the only one employing assumption A.6.
Lemma 4.2 Suppose that $\sqrt{n}\left(\varphi_{n}-b(\theta)\right)$ and $\sqrt{n}\left(\theta_{n}-\theta\right)$ admit locally uniform Edgeworth expansions of order s-2 over $\Theta^{\prime}$ the polynomials of the densities of which satisfy assumption A.4-EEQ and A.6 holds. Then $E\left(\varphi_{n}(\theta)\right)$ and $E\left(\theta_{n}(\theta)\right)$ are two times differentiable on $\Theta^{\prime}$ and for any $\theta \in \Theta^{\prime}$ and any sequence $\theta_{n} \neq \theta$ with values in $\Theta^{\prime}$ such that $\left\|\theta_{n}-\theta\right\| \leq C \frac{\ln ^{1 / 2} n}{n^{1 / 2}}$ for $C>0, i=1,2\left\|\frac{\partial M_{i_{n}}\left(\theta_{n}\right)}{\partial \theta^{\prime}}-K_{i}(\theta)\right\|=o(1)$ where $M_{1_{n}}(\theta)=E\left(\varphi_{n}(\theta)\right)$, $M_{2_{n}}(\theta)=E\left(\theta_{n}(\theta)\right), K_{1}=\frac{\partial b}{\partial \theta^{\prime}}, K_{2}=\mathrm{id}_{\mathbb{R}^{3}}$.

Proof. Consider first the case of $E\left(\varphi_{n}(\theta)\right)$. Let $\sigma\left(\varepsilon_{0}\right)$ the smallest sub $\sigma$-algebra of $\mathcal{F}$ w.r.t. the $\varepsilon_{0}, \varepsilon_{-1}, \ldots$ are measurable. We have that

$$
E\left(\varphi_{n}(\theta)\right)=E\left(E\left(\varphi_{n}(\theta) / \sigma\left(\varepsilon_{0}\right)\right)\right)
$$

Now notice that

$$
E\left(\varphi_{n}(\theta) / \sigma\left(\varepsilon_{0}\right)\right)=\int_{\mathbb{R}^{n}} \varphi_{n} \frac{1}{\sqrt{(2 \pi)^{n} \prod_{j=1}^{n} h_{i}(\theta)}} \exp \left(-\frac{1}{2} \sum_{i=1}^{n} \frac{y_{j}^{2}(\theta)}{h_{j}(\theta)}\right) d z
$$

and the differentiability result would follow via the dominated convergence theorem if

$$
E\left(\sup _{\theta \in \Theta^{\prime}}\left\|s_{n}(\theta)\right\|\right) \text { and } E\left(\sup _{\theta \in \Theta^{\prime}}\left\|H_{n}(\theta)\right\|\right)
$$

are finite where $s_{n}(\theta) \doteqdot \sum_{j=1}^{n}\left(\varepsilon_{j}^{2}-1\right) \frac{1}{h_{j}(\theta)} \frac{\partial h_{j}(\theta)}{\partial \theta}, H_{n}(\theta) \doteqdot \sum_{j=1}^{n}\left(\varepsilon_{j}^{2}-1\right) \frac{1}{h_{j}(\theta)} \frac{\partial^{2} h_{j}(\theta)}{\partial \theta \partial \theta^{\prime}}-$ $\sum_{j=1}^{n}\left(2 \varepsilon_{j}^{2}-1\right) \frac{1}{h_{j}^{2}(\theta)} \frac{\partial h_{j}(\theta)}{\partial \theta} \frac{\partial h_{j}(\theta)}{\partial \theta^{\prime}}, \bar{s}_{n}(\theta)=\frac{1}{n} s_{n}(\theta), \bar{H}_{n}(\theta)=\frac{1}{n} H_{n}(\theta)$. First notice that $h_{j}(\theta) \geq \underline{\eta}_{\omega}\left(1-\bar{\eta}_{\alpha}-\bar{\eta}_{\beta}\right) \doteqdot c_{*}$ and due to the fact that

$$
\begin{aligned}
& \frac{\partial h_{j}(\theta)}{\partial \theta_{1}}=\left(1-\theta_{2}-\theta_{3}\right)+\left(\theta_{2} \varepsilon_{j-1}^{2}+\theta_{3}\right) \frac{\partial h_{j-1}(\theta)}{\partial \theta_{1}} \\
& \frac{\partial h_{j}(\theta)}{\partial \theta_{2}}=-\theta_{1}+\varepsilon_{j-1}^{2} h_{j-1}(\theta)+\left(\theta_{2} \varepsilon_{j-1}^{2}+\theta_{3}\right) \frac{\partial h_{j-1}(\theta)}{\partial \theta_{2}}, \text { and } \\
& \frac{\partial h_{j}(\theta)}{\partial \theta_{3}}=-\theta_{1}+h_{j-1}(\theta)+\left(\theta_{2} \varepsilon_{j-1}^{2}+\theta_{3}\right) \frac{\partial h_{j-1}(\theta)}{\partial \theta_{3}}
\end{aligned}
$$

we have that

$$
\begin{aligned}
& E\left(\sup _{\theta \in \Theta^{\prime}}\left\|\sum_{j=1}^{n}\left(\varepsilon_{j}^{2}-1\right) \frac{1}{h_{j}(\theta)} \frac{\partial h_{j}(\theta)}{\partial \theta}\right\|\right) \\
\leq & \frac{1}{c_{*}} \sum_{j=1}^{n} E^{1 / 2}\left|\varepsilon_{j}^{2}-1\right|^{2} E^{1 / 2} \sup _{\theta \in \Theta^{\prime}}\left\|\frac{\partial h_{j}(\theta)}{\partial \theta}\right\|^{2}
\end{aligned}
$$

and for $\theta^{*}=\left(\bar{\eta}_{\omega}^{*}, \underline{\eta}_{\alpha}^{*}, \underline{\eta}_{\beta}^{*}\right)^{\prime}$ it is easy to see that

$$
E \sup _{\theta \in \Theta^{\prime}}\left\|\frac{\partial h_{j}(\theta)}{\partial \theta}\right\|^{2} \leq E\left\|\frac{\partial h_{j}\left(\theta^{*}\right)}{\partial \theta}\right\|^{2}<+\infty
$$

Furthermore, since

$$
\begin{aligned}
& \frac{\partial^{2} h_{j}(\theta)}{\partial \theta_{1}^{2}}=0 \\
& \frac{\partial^{2} h_{j}(\theta)}{\partial \theta_{2}^{2}}=-\theta_{1}+\varepsilon_{j-1}^{2} \frac{\partial h_{j}(\theta)}{\partial \theta_{2}}+\varepsilon_{j-1}^{2} \frac{\partial h_{j-1}(\theta)}{\partial \theta_{2}}+\left(\theta_{2} \varepsilon_{j-1}^{2}+\theta_{3}\right) \frac{\partial h_{j-1}(\theta)}{\partial \theta_{2}^{2}} \\
& \frac{\partial^{2} h_{j}(\theta)}{\partial \theta_{3}^{2}}=-\theta_{1}+2 \frac{\partial h_{j-1}(\theta)}{\partial \theta_{3}}+\left(\theta_{2} \varepsilon_{j-1}^{2}+\theta_{3}\right) \frac{\partial^{2} h_{j-1}(\theta)}{\partial \theta_{3}^{2}} \\
& \frac{\partial^{2} h_{j}(\theta)}{\partial \theta_{1} \partial \theta_{2}}=-1+\varepsilon_{j-1}^{2} \frac{\partial h_{j-1}(\theta)}{\partial \theta_{1}}+\left(\theta_{2} \varepsilon_{j-1}^{2}+\theta_{3}\right) \frac{\partial h_{j-1}(\theta)}{\partial \theta_{1} \partial \theta_{2}} \\
& \frac{\partial^{2} h_{j}(\theta)}{\partial \theta_{1} \partial \theta_{3}}=-1+\frac{\partial h_{j-1}(\theta)}{\partial \theta_{1}}+\left(\theta_{2} \varepsilon_{j-1}^{2}+\theta_{3}\right) \frac{\partial^{2} h_{j}(\theta)}{\partial \theta_{1} \partial \theta_{3}}
\end{aligned}
$$

we have that

$$
\begin{aligned}
& E\left(\sup _{\theta \in \Theta^{\prime}}\left\|\sum_{j=1}^{n}\left(\varepsilon_{j}^{2}-1\right) \frac{1}{h_{j}(\theta)} \frac{\partial^{2} h_{j}(\theta)}{\partial \theta \partial \theta^{\prime}}\right\|\right) \\
\leq & \frac{1}{c_{*}} \sum_{j=1}^{n} E^{1 / 2}\left|\varepsilon_{j}^{2}-1\right|^{2} E^{1 / 2}\left\|\frac{\partial^{2} h_{j}\left(\theta^{*}\right)}{\partial \theta \partial \theta^{\prime}}\right\|^{2}<+\infty
\end{aligned}
$$

and

$$
\begin{aligned}
& E\left(\sup _{\theta \in \Theta^{\prime}}\left\|\sum_{j=1}^{n}\left(2 \varepsilon_{j}^{2}-1\right) \frac{1}{h_{j}^{2}(\theta)} \frac{\partial h_{j}(\theta)}{\partial \theta} \frac{\partial h_{j}(\theta)}{\partial \theta^{\prime}}\right\|\right) \\
\leq & \frac{1}{c_{*}^{2}} \sum_{j=1}^{n} E^{1 / 2}\left|2 \varepsilon_{j}^{2}-1\right|^{2} E^{1 / 2}\left\|\frac{\partial h_{j}\left(\theta^{*}\right)}{\partial \theta}\right\|^{4}<+\infty
\end{aligned}
$$

Next notice that for any $\theta$ in $\Theta^{\prime}$ any $i=1, \ldots, 3$, and any sequence $\theta_{n}$ as described above we have that

$$
\begin{aligned}
& \left\|\frac{\partial E\left(\varphi_{n}\left(\theta_{n}\right)\right)}{\partial \theta_{i}}-\frac{\partial b(\theta)}{\partial \theta_{i}}\right\| \\
\leq & 2 \sup _{\theta^{*} \in \Theta^{\prime}}\left\|\frac{\partial^{2} E\left(\varphi_{n}\left(\theta^{*}\right)\right)}{\partial \theta_{i} \partial \theta^{\prime}}\right\|\left\|\theta_{n}-\theta\right\|+\left\|\frac{E\left(\varphi_{n}\left(\theta_{n}\right)\right)-E\left(\varphi_{n}(\theta)\right)}{\theta_{i_{n}}-\theta_{i}}-\frac{\partial b(\theta)}{\partial \theta_{i}}\right\|
\end{aligned}
$$

Then lemma 2.3 of Arvanitis and Demos [1] implies that due to the behavior of $\theta_{n}$ the last term on the right hand side of the last display is $o(1)$. Hence the result would follow if $\sup _{\theta^{*} \in \Theta^{\prime \prime}}\left\|\frac{\partial^{2} E\left(\varphi_{n}\left(\theta^{*}\right)\right)}{\partial \theta_{i} \partial \theta^{\prime}}\right\|=o\left(\frac{\sqrt{n}}{\ln ^{1 / 2} n}\right)$. The previous along with an application of the Cauchy-Schwarz and the triangle inequalities imply that for any $i$

$$
\begin{aligned}
& \sup _{\theta \in \Theta^{\prime}}\left\|\frac{\partial^{2} E\left(\varphi_{n}(\theta)\right)}{\partial \theta_{i} \partial \theta^{\prime}}\right\| \\
\leq & \sup _{\theta \in \Theta^{\prime}} E^{1 / 2}\left\|\varphi_{n}(\theta)-\theta\right\|^{2} \\
& \times\left(\sup _{\theta \in \Theta^{\prime}} E^{1 / 2}\left\|s_{n}(\theta) s_{n}^{\prime}(\theta)-E H_{n}(\theta)\right\|^{2}+\sup _{\theta \in \Theta^{\prime}} E^{1 / 2}\left\|H_{n}(\theta)-E H_{n}(\theta)\right\|^{2}\right)
\end{aligned}
$$

Furthermore, due to assumed Edgeworth approximation for $\sqrt{n}\left(\varphi_{n}(\theta)-\theta\right)$, and the fact that $s \geq 5$ lemma 3.1 of Arvanitis and Demos 1$]$ along with theorem 3.1 imply that $\sup _{\theta \in \Theta^{\prime}} E^{1 / 2}\left\|\left(\varphi_{n}-b(\theta)\right)\right\|^{2}=O\left(\frac{1}{\sqrt{n}}\right)$. Hence the result would follow if

$$
\begin{aligned}
\sup _{\theta \in \Theta^{\prime}} E\left\|n \bar{s}_{n}(\theta) \bar{s}_{n}^{\prime}(\theta)+E \bar{H}_{n}(\theta)\right\|^{2} & =o\left(\frac{n}{\ln n}\right) \\
\sup _{\theta \in \Theta^{\prime}} E\left\|\bar{H}_{n}(\theta)-E \bar{H}_{n}(\theta)\right\|^{2} & =o\left(\frac{n}{\ln n}\right)
\end{aligned}
$$

From the proof of Lemma A. 1 of Corradi and Inglesias [6], we can prove that $\sqrt{n}\left(S_{n}^{*}(\theta)-E\left(S_{n}^{*}(\theta)\right)\right)$, where $S_{n}^{*}$ contains stacked the elements of $\bar{s}_{n}$ and $\bar{H}_{n}$ admits a locally uniform Edgeworth expansion of order $s-4$ over $\Theta^{\prime}$ by establishing the conditions A.2.M-WD and A.3.EL-CPD through the provision of bounds independent of $\theta$ using the compactness of $\Theta^{\prime}$ and condition
A.3-NDD using the result of the referenced proof, the $P$ almost everywhere continuity of the elements of $S_{n}^{*}(\theta)$ on $\Theta^{\prime}$, the continuity of det and the compactness of $\Theta^{\prime}$. Then the remark immediately after the proof of lemma 3.1 of Arvanitis and Demos [1] implies that

$$
\begin{aligned}
\sup _{\theta \in \Theta^{\prime}} E\left\|n \bar{s}_{n}(\theta) \bar{s}_{n}^{\prime}(\theta)+E \bar{H}_{n}(\theta)\right\|^{2} & =O(1) \\
\sup _{\theta \in \Theta^{\prime}} E\left\|\bar{H}_{n}(\theta)-E \bar{H}_{n}(\theta)\right\|^{2} & =O\left(\frac{1}{n}\right)
\end{aligned}
$$

which establish the needed bounds. The result about $E\left(\theta_{n}(\theta)\right)$ is derived analogously.

We are now ready to prove the main proposition.
Proof. Notice first that uniform consistency of $\varphi_{n}$ to $b(\theta)$ along with the boundness of $\Theta$ imply by uniform integrability that

$$
\begin{equation*}
\sup _{\theta \in \Theta}\left|E_{\theta} \varphi_{n}-b(\theta)\right|=o(1) \tag{31}
\end{equation*}
$$

hence for any $\varepsilon>0$

$$
\begin{aligned}
& \sup _{\theta^{*} \in \Theta} P\left(\sup _{\theta \in \Theta} \|\left|\varphi_{n}-E \varphi_{n}(\theta)\right|-\left|b\left(\theta^{*}\right)-b(\theta)\right| \mid>\varepsilon\right) \\
\leq & \sup _{\theta^{*} \in \Theta} P\left(\left|\varphi_{n}-b\left(\theta^{*}\right)\right|+o(1)>\varepsilon\right)=o\left(n^{-\frac{s-2}{2}}\right)
\end{aligned}
$$

due to the analogous consistency of $\varphi_{n}$. Hence

$$
\sup _{\theta^{*} \in \Theta} P\left(\varphi_{n}^{*} \in \mathcal{O}\left(\theta^{*}, \varepsilon\right) \cap \Theta\right)=1-o\left(n^{-\frac{s-2}{2}}\right)
$$

for any $\varepsilon>0$. Then from lemma 4.2 and the proofs of lemma 2 and lemma 2.4 of Arvanitis and Demos [1] we obtain that

$$
\begin{equation*}
\sup _{\theta^{*} \in \Theta^{\prime \prime}} P\left(\sqrt{n}\left|\varphi_{n}^{*}-\theta\right|>C \ln ^{1 / 2} n\right)=o\left(n^{-\frac{s-2}{2}}\right) \tag{32}
\end{equation*}
$$

for some appropriate $C>0$. Now using remark (2.12) and paragraph 4 of Gotze and Hipp [8] we obtain that the $a_{r, j+r}$ terms that structure the cumulant asymptotic expansions for $S_{n}$ and thereby the coefficients of the polynomials and the quadratic form in the relevant Edgeworth density are smooth functions of power series of the form $c(\theta) \sum_{i_{1}, i_{2}, i_{3}, \ldots=0}^{\infty} x_{1}^{i_{1}} x_{2}^{i_{2}} x_{3}^{i_{3}} \ldots$ where $c(\theta)$ is $s$ times continuously differentiable for any $\theta$ in $\Theta^{\prime \prime}$ due to the fact that it is obtained as a smooth function of moments of products of powers of
elements of $X_{0}$ of order less that or equal to $s+2$ which are $s$ times continuously differentiable for any $\theta$ in $\Theta^{\prime \prime}$ by dominated convergence. Furthermore, $x_{i_{j}}$ is of the form $E\left(\theta_{2}\left|\varepsilon_{0}\right|^{s_{1}}+\theta_{3} \varepsilon_{0}^{s_{2}}\right)^{s_{3}}$ where $s_{1} s_{3}, s_{2} s_{3} \leq 2 s+2$ hence the previous power series is $s$ times continuously differentiable inside the relevant unit ball and $x_{i_{j}}$ is $s$ times continuously differentiable for any $\theta$ in $\Theta^{\prime \prime}$ again due to dominated convergence. Hence the coefficients of the polynomials and the quadratic form in the in the formal Edgeworth density of $S_{n}$ are $s$ times continuously differentiable for any $\theta$ in $\Theta^{\prime \prime}$. This along with the analogous differentiability of $f$ in the proof of proposition 2 imply that the $\pi_{i}$ there are also $s$ times continuously differentiable for any $\theta$ in $\Theta^{\prime \prime}$ for any $z \in \mathbb{R}$. Then dominated convergence implies the same for $\mathcal{I}_{V}\left(k_{i}(z, \theta)\right)$ for all $i=1, \ldots, s+2$. Then lemma 2.3 of Arvanitis and Demos [1] implies that for any stochastic sequence $\widetilde{\theta}_{n}$ for which

$$
\sup _{\theta \in \Theta^{\prime \prime}} P\left(\sqrt{n}\left|\widetilde{\theta}_{n}-\theta\right|>C \ln ^{1 / 2} n\right)
$$

then

$$
\sup _{\theta \in \Theta^{\prime \prime}} P\left(\left\|\sqrt{n}\left(E_{\widetilde{\theta}_{n}} \varphi_{n}-E_{\theta} \varphi_{n}\right)-A_{n}(\theta)\right\|>\gamma_{n}\right)=o\left(n^{-\frac{s-2}{2}}\right)
$$

where
$A_{n}(\theta)=\sum_{j=0}^{s-2} \frac{1}{n^{\frac{j}{2}}(j+1)!} D^{j+1}\left(b(\theta)+\sum_{k=1}^{s-2-j} \frac{\mathcal{I}_{V}\left(k_{k}(z, \theta)\right)}{n^{\frac{k}{2}}}\right)\left(\sqrt{n}\left(\widetilde{\theta}_{n}-\theta\right)^{j+1}\right)$
and $\gamma_{n}=o\left(n^{-a}\right)$ independent of $\theta$. This along with lemma 4.2 imply that $\frac{\partial E \varphi_{n}\left(\varphi_{n}^{*}\right)}{\partial \theta}$ converges to $\frac{\partial b(\theta)}{\partial \theta^{\prime}}$ for any $\theta$ in $\Theta^{\prime \prime}$ with probability $1-o\left(n^{-\frac{s-2}{2}}\right)$ independent of $\theta$, hence with the same probability $\varphi_{n}^{*}$ satisfies $\varphi_{n}=E_{\varphi_{n}^{*}} \varphi_{n}$. Hence with probability $1-o\left(n^{-\frac{s-2}{2}}\right)$ independent of $\theta, \varphi_{n}^{*}$ satisfies

$$
0=\sqrt{n}\left(\varphi_{n}-E_{\theta} \varphi_{n}^{*}\right)+A_{n}(\theta)+R_{n}(\theta)
$$

and the result follows from 32, proposition 4.1, lemma AL.2 and theorem 3.2. The case of $\theta_{n}^{*}$ follows in complete analogy to the previous by simply replacing in the previous proof any invocation to $f$ with $b^{-1}(\varphi)=$ $\left(\varphi_{1}, \frac{1-\varphi_{3}^{2}-\sqrt{\left(1-\left(2 \varphi_{2}-\varphi_{3}\right)^{2}\right)\left(1-\varphi_{3}^{2}\right)}}{2\left(\varphi_{2}-\varphi_{3}\right)}, \frac{-\left(1-2 \varphi_{2} \varphi_{3}+\varphi_{3}^{2}\right)+\sqrt{\left(1-\left(2 \varphi_{2}-\varphi_{3}\right)^{2}\right)\left(1-\varphi_{3}^{2}\right)}}{2\left(\varphi_{2}-\varphi_{3}\right)}\right)$ and of $b$ with the identity.

Remark R. 4 Notice that $\theta_{n}^{*}$ can be shown to be locally uniformly second order unbiased (i.e. $\sup _{\theta \in \Theta^{\prime \prime}}\left\|E_{\theta} \theta_{n}^{*}-\theta\right\|=o\left(n^{-1}\right)$ ) something that is not the case for $\theta_{n}$ or $\varphi_{n}^{*}$, even though the three estimators posses the same second order MSE uniformly over $\Theta^{\prime \prime}$ (see Arvanitis and Demos [1] Corollary 2 and Lemma 3.6).

## 5 Conclusions

We have established sufficient conditions for the existence of locally uniform Edgeworth expansions under weak dependence and/or smooth transformations. These extend analogous pointwise results in the relevant literature and can be applied for the establishment of high order asymptotic properties of estimators arising in the context of eligible stochastic processes. Special cases are M-estimators defined by the expectation of auxiliary ones. In these cases the results enable the polynomial approximation of the equations that are asymptotically satisfied by the estimators without the use of higher order derivatives, something that avoids the establishment of issues such as their rates of convergence. The interest on these estimators lies on the fact that under appropriate conditions they can possess desirable higher order properties. A question for future research concerns the issue of establishing Edgeworth type expansions (see Magdalinos [11]) when $\theta$ lies in the boundary of the parameter space.
